

# Comparison of different SQL implementations

The goal of this page — which is a **work in progress** — is to gather information relevant for people who are porting SQL from one product to another and/or are interested in possibilities and limits of 'cross-product' SQL.

The following tables compare how different DBMS products handle various SQL (and related) features. If possible, the tables also state how the implementations *should* do things, according to the SQL standard.

I will only write about subjects that I've worked with personally, or subjects which I anticipate to find use for in the near future. Subjects on which there are no significant implementation variances are not covered. Beta-versions of software are not examined.

I'm sorry about the colors. They are a result of wanting to mark each DBMS differently and at the same time wanting to be relatively nice to printers.

If you have corrections or suggestions, please contact me; even notifications about spelling errors are welcome.

## Legend, definitions, and notes

The following SQL standard and implementations have been examined, if not otherwise stated:

Standard	<p>The latest official version of SQL is SQL:2008.</p> <p>I don't have access to the official ISO standard text, but Whitemarsh Information Systems Corporation provides a rather final draft as a zip-archive, containing several files. Most important to this page is the file <a href="#">5CD2-02-Foundation-2006-01.pdf</a>.</p> <p>No books cover SQL:2008 yet. Regarding the previous standard, SQL:2003, the only book covering the subject is in German which I was never any good at. Therefore, I also use the following book as reference: Jim Melton and Alan Simon: <i>SQL:1999—Understanding Relational Language Components</i> (ISBN 1-55860-456-1).</p>
PostgreSQL	<p>PostgreSQL 8.4.1 on CentOS Linux. <a href="#">DOCUMENTATION</a></p>
DB2	<p>DB2 Express-C v. 9.1 on Fedora Linux. Note that there are differences between various DB2 flavors; this page is about DB2 for "LUW" (Linux/Unix/Windows). <a href="#">DOCUMENTATION</a></p>
MS SQL Server	<p>MS SQL Server 2005 on Windows XP. Microsoft's SQL implementation is sometimes named <i>Transact-SQL</i>, or <i>TSQL</i>. In this document, I'll generally write <i>MSSQL</i> as a short-hand for Microsoft's SQL Server product. <a href="#">DOCUMENTATION</a></p>
MySQL	<p>MySQL Database Server 5.0.18 on Fedora Linux (i.e. MySQL AB's "classic" DBMS product—not MaxDB). <a href="#">DOCUMENTATION</a></p>
Oracle	<p>Oracle Database 11g Release 2 on Red Hat Enterprise Linux. <a href="#">DOCUMENTATION</a></p>
Informix	<p>Informix Dynamic Server Workgroup Edition v. 11.50 on Red Hat Enterprise Linux. <a href="#">DOCUMENTATION</a></p>

The products are running with their default settings. This is important for MySQL and MSSQL: Their interpretation of SQL may be changed rather drastically by adjusting certain configuration options, potentially increasing the level of standard compliance (for MySQL, there is a dedicated documentation page about this). However, such non-default configuration options are not of great value for people writing SQL applications because the developer often cannot rely on non-default configuration settings.

## Features

### Views

Standard	<p>Views are part of the standard, and they may be updated, as long as it 'makes sense'.</p> <p>SQL:2008 has a rather complicated set of rules governing when a view is updatable, basically saying that a view is updatable, as long as the update-operation translates into an unambiguous change.</p> <p>SQL-92 was more restrictive, specifying that updatable views cannot be derived from more than one base table.</p>
PostgreSQL	Has views. Breaks that standard by not allowing updates to views; offers the non-standard 'rules'-system as a workaround.
DB2	Conforms to at least SQL-92.
MSSQL	Conforms to at least SQL-92.
MySQL	Conforms to at least SQL-92.
Oracle	Conforms to at least SQL-92.
Informix	Conforms to at least SQL-92.

### Join types and features

All the DBMSes support basic INNER JOINs, but vary in their support for other join types.

In the following feature chart, a ✓ means yes; an empty table cell means no.

<b>FULL joins<sup>1</sup> (tested: <code>SELECT ... FULL JOIN ... ON ... = ...</code>)</b>	✓	✓	✓	✓	✓	✓
<b>Explicit CROSS JOIN (cartesian product)</b>	✓	✓	✓	✓	✓	✓

Remarks:

1. Note that **FULL** joins may be emulated with a union of a left and a right join.

## Data definition language (DDL)

### Copying structure

Objective: An existing table, *t1* needs to be copied to a new table, *t2*, *without* copying data. I.e., only the structure/definition of the table is copied.

Standard	<p>Optional feature T171 defines <i>LIKE clause in table definition</i>:</p> <pre>CREATE TABLE t2 ( LIKE t1 )</pre> <p>The DBMS may support an extension of this (feature T173) which allows for more table properties to be copied:</p> <pre>CREATE TABLE t2 ( LIKE t1 INCLUDING IDENTITY INCLUDING DEFAULTS INCLUDING GENERATED )</pre> <p>If <code>INCLUDING DEFAULTS</code> is not specified, column defaults will not be part of <i>t2</i>; likewise with <code>IDENTITY</code> and <code>GENERATED</code> properties.</p> <p>Triggers, CHECK constraints, and other 'non-trivial' table features are not copied to the new table.</p>
PostgreSQL	<p>Complies with the core of the feature (T171). The extended T173 feature is only partially supported, and extended with a few non-standard options:</p> <ul style="list-style-type: none"> <li>• The <code>INCLUDING IDENTITY</code> and <code>INCLUDING GENERATED</code> options are not supported</li> <li>• <code>INCLUDING CONSTRAINTS</code> and <code>INCLUDING INDEXES</code> options are added</li> </ul> <p>PostgreSQL does not allow you to copy the structure of a view, using <code>CREATE TABLE ... (LIKE ...)</code>. For that, you may use another construct:</p> <pre>CREATE TABLE copytable AS SELECT * FROM viewname WHERE false</pre> <p>DOCUMENTATION</p>
DB2	<p>Behaves as if <i>inspired by</i> the standard. I.e., DB2 conforms to the standard, except:</p> <ul style="list-style-type: none"> <li>• the <code>LIKE ...</code> clause is stated <i>outside</i> any parenthesis</li> <li>• the extended <code>INCLUDING GENERATED</code> option is not supported</li> <li>• DB2 defaults to copy <code>IDENTITY</code>, <code>DEFAULTS</code>, and <code>GENERATED</code> properties, unless <code>EXCLUDING IDENTITY</code> and/or <code>EXCLUDING DEFAULTS</code> is specified.</li> </ul> <p>Example:</p> <pre>CREATE TABLE t2 LIKE t1 INCLUDING DEFAULTS</pre> <p>DB2 allows you to copy the structure of a view into a table.</p> <p>DOCUMENTATION</p>
MSSQL	<p>Does not support the standard. Instead, MSSQL has a special <code>SELECT ... INTO ... FROM ...</code> construct which can be combined with an impossible <code>WHERE</code>-clause to copy structure only:</p> <pre>SELECT * INTO t2 FROM t1 WHERE 1&lt;&gt;1</pre> <p>The source (<i>t1</i>) may be a view, as well as a table.</p> <pre>SELECT ... INTO copies NOT NULL column attributes, but nothing else.</pre> <p>DOCUMENTATION</p>
MySQL	<p>Complies with the core of the feature (T171), but not with the extended features (T173).</p> <p>MySQL does not allow you to copy the structure of a view into a table.</p> <p>DOCUMENTATION</p>
Oracle	<p>Does not support the standard. Oracle lets you copy a table structure using a special <code>CREATE TABLE ... AS</code> construct, combined with an impossible <code>WHERE</code>-clause: <code>CREATE TABLE t2 AS SELECT * FROM t1 WHERE 1&lt;&gt;1</code></p> <p>DOCUMENTATION</p>
Informix	On my TODO.

## Ordering result sets

Standard	<p>The SQL-standard states that relations are unordered, but result sets may be ordered when returned to the user through a cursor:</p> <pre>DECLARE cursorname CURSOR FOR     SELECT ... FROM ... WHERE ...     ORDER BY column_name1, column_name2, ...</pre> <p>The DBMS may additionally allow <code>ORDER BY</code> outside cursor definitions (optional feature IDs F850, F851, F852, F855). (Since SQL:2008)</p> <p>The standard doesn't specify how NULLs should be ordered in comparison with non-NULL values, except that any two NULLs are to be considered equally ordered, and that NULLs should sort either above or below all non-NULL values. However, the DBMS may optionally (as part of feature ID T611, "Elementary OLAP operations") allow the user to specify whether NULLs should sort first or last:</p> <pre>... ORDER BY ... NULLS FIRST or ... ORDER BY ... NULLS LAST</pre>
PostgreSQL	<p>As well as in cursor definitions, it allows <code>ORDER BY</code> in other contexts.</p> <p>By default, NULLs are considered <b>higher</b> than any non-NULL value; however, (since version 8.3) this sorting behaviour may be changed by adding <code>NULLS FIRST</code> or <code>NULLS LAST</code> to the <code>ORDER BY</code> expression.</p> <p><a href="#">DOCUMENTATION</a></p>
DB2	<p>As well as in cursor definitions, it allows <code>ORDER BY</code> in other contexts. NULLs are considered <b>higher</b> than any non-NULL value.</p> <p><a href="#">DOCUMENTATION</a></p>
MSSQL	<p>As well as in cursor definitions, it allows <code>ORDER BY</code> in other contexts. NULLs are considered <b>lower</b> than any non-NULL value.</p> <p><a href="#">DOCUMENTATION</a></p>
MySQL	<p>As well as in cursor definitions, it allows <code>ORDER BY</code> in other contexts.</p> <p>NULLs are considered <b>lower</b> than any non-NULL value, except if a - (minus) character is added before the column name and ASC is changed to DESC, or DESC to ASC; this minus-before-column-name feature seems undocumented.</p> <p><a href="#">DOCUMENTATION</a></p>
Oracle	<p>As well as in cursor definitions, it allows <code>ORDER BY</code> in other contexts.</p> <p>By default, NULLs are considered <b>higher</b> than any non-NULL value; however, this sorting behaviour may be changed by adding <code>NULLS FIRST</code> or <code>NULLS LAST</code> to the <code>ORDER BY</code> expression.</p> <p>Beware of Oracle's strange treatment of empty strings and NULLs as the same 'value'.</p> <p><a href="#">DOCUMENTATION</a></p>
Informix	<p>As well as in cursor definitions, it allows <code>ORDER BY</code> in other contexts. NULLs are considered <b>lower</b> than any non-NULL value.</p> <p><a href="#">DOCUMENTATION</a></p>

## Limiting result sets

### Simple limit

Objective: Want to only get  $n$  rows in the result set. Usually only makes sense in connection with an `ORDER BY` expression.

Note: This is **not** the same as a *top-n* query — see next section.

Note also: Some of the queries below may not be legal in all situations, such as in views or sub-queries.

Standard	<p>The SQL standard provides three ways of performing a 'simple limit':</p> <ul style="list-style-type: none"> <li>• Using <code>FETCH FIRST</code>. (since SQL:2008)</li> </ul> <p>Non-core feature IDs F856 F857 F858 and F859 describe using</p>
----------	---

- Using a **Window function**: (since SQL:2003)

Non-core Feature ID T611 specifies *window functions*, of which one is `ROW_NUMBER() OVER`:

```
SELECT * FROM (
  SELECT
    ROW_NUMBER() OVER (ORDER BY key ASC) AS rownumber,
    columns
  FROM tablename
) AS foo
WHERE rownumber <= n
```

- Using a **cursor**:

If your application is stateful (in contrast to web applications which normally have to be seen as stateless), then you might look at *ursors* (core feature ID E121) instead. This involves:

- o `DECLARE cursor-name CURSOR FOR ...`
- o `OPEN cursor-name`
- o `FETCH ...`
- o `CLOSE cursor-name`

PostgreSQL	Supports all standards-based approaches.
------------	--

In old PostgreSQL versions (versions 8.3 and older), a special PostgreSQL (and MySQL) specific method was used:

```
SELECT columns
FROM tablename
ORDER BY key ASC
LIMIT n
```

Note that `LIMIT` changes the semantics of `SELECT...FOR UPDATE`.

Documentation:

- `FETCH FIRST/LIMIT`
- `WINDOW FUNCTIONS`

DB2	Supports all standards-based approaches.
-----	--

Documentation:

- OLAP functions
- `FETCH FIRST` (general page about the `SELECT` statement; use your browser's search function to locate `FETCH FIRST`)

MSSQL	<p>Supports the <code>ROW_NUMBER()</code> (since MSSQL 2005) and cursor standards-based approaches; doesn't support <code>FETCH FIRST</code>.</p> <p>MSSQL 2000 didn't support <code>ROW_NUMBER()</code>. Instead, a MSSQL 2000-specific syntax was needed:</p> <pre>SELECT TOP n columns FROM tablename ORDER BY key ASC</pre> <p>The <code>TOP</code> construct is still available in MSSQL 2008, and it's handy for casual SQL work.</p> <p>DOCUMENTATION</p>
-------	--

MySQL	<p>Doesn't support the standard. Alternative solution:</p> <pre>SELECT columns FROM tablename ORDER BY key ASC LIMIT n</pre> <p>DOCUMENTATION</p>
-------	---

Oracle	<p>Supports <code>ROW_NUMBER</code>; doesn't support <code>FETCH FIRST</code>.</p> <p>As Oracle doesn't allow <code>AS</code> for subquery naming (and doesn't need a subquery-name at all in this case), the standard SQL code above needs to be rewritten slightly:</p> <pre>SELECT * FROM (   SELECT</pre>
--------	---

```
WHERE rownumber <= n
```

## DOCUMENTATION

A reader of this page told me that using the Oracle-specific `ROWNUM` 'magic' column yields better performance than using the `ROW_NUMBER` function. You may want to experiment with this. Ask Tom has an article on `ROWNUM`.

## Informix

Supports neither `ROW_NUMBER()`, nor `FETCH FIRST`.

Alternative solution (which is illegal in plain sub-queries):

```
SELECT FIRST n columns
FROM tablename
ORDER BY key ASC
```

## DOCUMENTATION

**Top-n query**

Objective: Like the simple limit-query above, but include rows with tie conditions. Thus, the query may return more than  $n$  rows.

Some call this a *quota*-query.

The following examples are based on this table:

```
SELECT * FROM person ORDER BY age ASC;
```

PERSON_ID	PERSON_NAME	AGE
7	Hilda	12
8	Bill	12
4	Joe	23
2	Veronica	23
3	Michael	27
9	Marianne	27
1	Ben	50
10	Michelle	50
5	Irene	77
6	Vivian	77

Now, we only want the three ( $n=3$ ) youngest persons displayed, i.e. a result set like this:

PERSON_ID	PERSON_NAME	AGE
7	Hilda	12
8	Bill	12
4	Joe	23
2	Veronica	23

## Standard

With standard SQL, there are two principal ways to obtain the wanted data:

- The **fast** variant:

One of the major additions in SQL:2003 was the addition of non-core (i.e. optional) OLAP (online analytic processing) features. If the DBMS supports elementary OLAP (feature ID F611), then the top- $n$  query may be formulated using a *window function*, such as `RANK() OVER`:

```
SELECT * FROM (
  SELECT
    RANK() OVER (ORDER BY age ASC) AS ranking,
    person_id,
    person_name,
    age
  FROM person
) AS foo
WHERE ranking <= 3
```

(Change `ASC` to `DESC` in the position marked *like this* in order to get a *top-3 oldest* query instead.)

- The **slow** variant:

*Queries) by Fabian Pascal (who, again, quotes Date for the solution):*

```
SELECT * FROM person AS px
WHERE (
    SELECT COUNT(*)
    FROM person AS py
    WHERE py.age < px.age
) < 3
```

The query may make more sense if the objective is re-phrased as "Find all persons (px) such that the number of younger, other persons (py) is less than 3".

(Change < to > in the position marked **like this** in order to get a *top-3 oldest* query instead.)

In the article *Going To Extremes* by Joe Celko, there is a description of yet another principle for performing quota queries, using *scalar subqueries*. Scalar subqueries are more tedious to write but might yield better performance on your system.

PostgreSQL	<p>Supports the fast standard SQL variant.</p> <p>In version 8.3 and older, PostgreSQL only supported the slow standard SQL query variant. In practice, a PostgreSQL-only method was used instead, in order to obtain acceptable query performance:</p> <pre>SELECT * FROM person WHERE (     age &lt;= (         SELECT age FROM person         ORDER BY age ASC         LIMIT 1 OFFSET 2      -- 2=n-1     ) ) IS NOT FALSE</pre> <p>(Change &lt;= to &gt;= and ASC to DESC in the positions marked <b>like this</b> in order to get a <i>top-3 oldest</i> query instead.)</p> <p>DOCUMENTATION</p>
DB2	<p>Supports the fast standard SQL variant.</p> <p>DOCUMENTATION</p>
MSSQL	<p>Supports the fast standard SQL variant.</p> <p>MSSQL 2000 supported the slow standard SQL variant. In practice, a MSSQL-only expression had to be used instead, in order to obtain acceptable query performance:</p> <pre>SELECT TOP 3 WITH TIES * FROM person ORDER BY age ASC</pre> <p>(Change ASC to DESC in the position marked <b>like this</b> in order to get a <i>top-3 oldest</i> query instead.)</p> <p>DOCUMENTATION</p>
MySQL	<p>Supports the slow standard SQL solution. In practice, this MySQL-specific solution should be used instead, in order to obtain acceptable query performance:</p> <pre>SELECT * FROM person WHERE age &lt;= COALESCE( -- note: no space between "COALESCE" and opening parenthesis     (         SELECT age         FROM person         ORDER BY age ASC         LIMIT 1 OFFSET 2      -- 2=n-1     ),     (         SELECT MAX(age)         FROM person     ) )</pre> <p>(Change &lt;= to &gt;= and ASC to DESC and MAX to MIN in the positions marked <b>like this</b> in order to get a <i>top-3 oldest</i> query instead.)</p> <p>The offset-value 2 is the result of <math>n-1</math> (remember: <math>n</math> is 3 in these examples).</p>

naming of subqueries), the query has to be paraphrased slightly:

```
SELECT * FROM (
  SELECT
    RANK() OVER (ORDER BY age ASC) AS ranking,
    person_id,
    person_name,
    age
  FROM person
)
WHERE ranking <= 3

(Change ASC to DESC in the position marked like this in order to get a top-3 oldest query instead.)
```

DOCUMENTATION

Informix On my TODO.

## Limit—with offset

Objective: Want to only get ***n*** rows in the result set, and we want the first ***skip*** rows in the result set discarded. Usually only makes sense in connection with an `ORDER BY` expression.

In the recipes below, basic ordering is ASCending, i.e. lowest-first queries. If you want the opposite, then change `ASC->DESC` and `DESC->ASC` at the places emphasized **like this**.

Standard	<p>The SQL standard provides three ways of performing 'limit with offset':</p> <ul style="list-style-type: none"> <li>Using <code>OFFSET</code> and <code>FETCH FIRST</code>: (since SQL:2008)</li> </ul> <pre>SELECT... FROM ... WHERE ... ORDER BY ... OFFSET <b>skip</b> ROWS FETCH FIRST <b>n</b> ROWS ONLY</pre> <p>You may write <code>ROW</code> instead of <code>ROWS</code>.</p> <ul style="list-style-type: none"> <li>Using a <b>window function</b>: (since SQL:2003)</li> </ul> <p>Non-core Feature ID T611 specifies <i>window functions</i>, one of which is <code>ROW_NUMBER()</code> <code>OVER</code>:</p> <pre>SELECT * FROM (   SELECT     ROW_NUMBER() OVER (ORDER BY key ASC) AS rounum,     columns   FROM tablename ) AS foo WHERE rounum &gt; <b>skip</b> AND rounum &lt;= (<b>n+skip</b>)</pre> <ul style="list-style-type: none"> <li>Using a <b>cursor</b>:</li> </ul> <p>You may use a <b>cursor</b> (core feature ID E121), if the programming environment permits it. This involves:</p> <ul style="list-style-type: none"> <li>• <code>DECLARE cursor-name CURSOR FOR ...</code></li> <li>• <code>OPEN cursor-name</code></li> <li>• <code>FETCH RELATIVE number-of-rows-to-skip ...</code></li> <li>• <code>CLOSE cursor-name</code></li> </ul>
PostgreSQL	<p>Supports all the standards-based approaches.</p> <p>In version 8.3 and older, cursors should be used, or a special construct:</p> <pre>SELECT columns FROM tablename ORDER BY key ASC LIMIT <b>n</b> OFFSET <b>skip</b></pre> <p>Documentation:</p>

	<p>Supports the <i>window function</i> based approach.</p> <p>Regarding cursors: DB2 for Linux/Unix/Windows doesn't support <code>FETCH RELATIVE</code> (which is strange, because DB2 for the mainframe seems to support it). Instead, see if the DB2 driver for your programming environment supports <code>SQLFetchScroll()</code>.</p> <p>DOCUMENTATION: OLAP functions, the <code>FETCH</code> statement.</p>
MSSQL	<p>Supports the <i>window function</i> and cursor based approaches.</p> <p>MSSQL 2000 didn't support <code>ROW_NUMBER()</code>; instead, a MSSQL-specific syntax had to be used:</p> <pre>SELECT * FROM (     SELECT TOP n * FROM (         SELECT TOP z columns      -- (z=n+skip)         FROM tablename         ORDER BY key ASC     ) AS FOO ORDER BY key DESC -- ('FOO' may be anything) ) AS BAR ORDER BY key ASC -- ('BAR' may be anything)</pre> <p>DOCUMENTATION</p>
MySQL	<p>Doesn't support the standard approaches. Alternative solution:</p> <pre>SELECT columns FROM tablename ORDER BY key ASC LIMIT n OFFSET skip</pre> <p>In older versions of MySQL, the <code>LIMIT</code>-syntax is less clear:</p> <pre>... LIMIT [skip,] n</pre> <p>(i.e. the <code>skip</code> argument is optional).</p> <p>The old syntax is still supported by later MySQL versions (the old syntax is widely used).</p> <p>DOCUMENTATION</p>
Oracle	<p>Supports <code>ROW_NUMBER()</code>. I'm unsure if Oracle's cursor support is standards-compliant.</p> <p>As Oracle doesn't accept <code>AS</code> for subquery naming (and doesn't require naming of subqueries in this case), the standard SQL solution has to be re-written slightly. An other reason for the rewrite is that <code>ROWNUM</code> is a reserved word in Oracle, with special meaning. The Oracle code becomes:</p> <pre>SELECT * FROM (     SELECT         ROW_NUMBER() OVER (ORDER BY key ASC) AS rn,         columns     FROM tablename ) WHERE rn &gt; skip AND rn &lt;= (n+skip)</pre> <p>DOCUMENTATION</p> <p>A reader of this page told me that using the Oracle-specific <code>ROWNUM</code> 'magic' column yields better performance than using the <code>ROW_NUMBER</code> function. You may want to experiment with this. Ask Tom has an article on <code>ROWNUM</code>.</p>
Informix	<p>Supports neither <code>OFFSET...FETCH FIRST</code> nor <code>ROW_NUMBER</code>. Supports cursors.</p> <p>An alternative to using cursors is to use an Informix-specific construct:</p> <pre>SELECT SKIP skip FIRST n * FROM tablename</pre> <p>DOCUMENTATION: <code>SKIP</code> and <code>FIRST</code></p>

Note:

`FETCH FIRST/LIMIT/TOP` queries with offset are often used in a result presentation context: To retrieve only—say—30 rows at a time so that the end-user isn't overwhelmed by the complete result set, but instead is offered a paginated result presentation. In this case, be careful not to (only) sort on a non-unique column.

Consider the following example (where PostgreSQL is used):

```
SELECT * FROM person ORDER BY age ASC;
person_id | person_name | age
-----+-----+-----+
7 | Hilda | 12
```

10	Michelle	50
5	Irene	77
6	Vivian	77

When ordering is performed on the non-unique age-value, ties may occur and it's not guaranteed that the DBMS will fetch the rows in the same order every time.

Instead of the above listing, the DBMS is allowed to return the following display order where Michael and Marianne are displayed in the opposite order compared to above:

```
SELECT * FROM person ORDER BY age ASC;
+-----+-----+-----+
| person_id | person_name | age |
+-----+-----+-----+
| 7 | Hilda | 12 |
| 8 | Bill | 12 |
| 4 | Joe | 23 |
| 2 | Veronica | 23 |
| 9 | Marianne | 27 |
| 3 | Michael | 27 |
| 1 | Ben | 50 |
| 10 | Michelle | 50 |
| 5 | Irene | 77 |
| 6 | Vivian | 77 |
```

Now, suppose the end-user wants the results displayed five rows at a time. The result set is fetched in two queries where the DBMS happens to sort differently, as above. We will use PostgreSQL's legacy syntax in the example:

```
SELECT * FROM person ORDER BY age ASC LIMIT 5;
+-----+-----+-----+
| person_id | person_name | age |
+-----+-----+-----+
| 7 | Hilda | 12 |
| 8 | Bill | 12 |
| 4 | Joe | 23 |
| 2 | Veronica | 23 |
| 3 | Michael | 27 |

SELECT * FROM person ORDER BY age ASC LIMIT 5 OFFSET 5;
+-----+-----+-----+
| person_id | person_name | age |
+-----+-----+-----+
| 3 | Michael | 27 |
| 1 | Ben | 50 |
| 10 | Michelle | 50 |
| 5 | Irene | 77 |
| 6 | Vivian | 77 |
```

Notice that Marianne was not displayed in any of the two split result set presentations.

The problem could be avoided if the result set ordering had been done in a deterministic way, i.e. where the unique person\_id value was considered in case of a tie:

```
SELECT * FROM person ORDER BY age ASC, person_id ASC ...
```

This is safer than to pray for the DBMS to behave in a predictable way when handling non-unique values.

**Note:** If the table is updated between parts of the result set pagination, then the user might still get an inconsistent presentation. If you want to guard against this, too, then you should see if use of an *insensitive* cursor is an option in your application. Use of cursors to paginate result sets usually require that your application is *stateful*, which is *not* the case in many web-application settings. Alternatively, you could let the application cache the complete result set (e.g. in a session) if your web application environment provides for sessions).

## The INSERT statement

### Inserting several rows at a time

Standard	An optional SQL feature is <i>row value constructors</i> (feature ID F641). One handy use of row value constructors is when inserting several rows at a time, such as:  <pre>INSERT INTO tablename VALUES (0,'foo') , (1,'bar') , (2,'baz');  — which may be read as a shorthand for  INSERT INTO tablename VALUES (0,'foo'); INSERT INTO tablename VALUES (1,'bar'); INSERT INTO tablename VALUES (2,'baz');</pre>
PostgreSQL	<b>Supported.</b> (since version 8.2)
DB2	<b>Supported.</b>
MSSQL	<b>Supported.</b> (since version 2008)
MySQL	<b>Supported.</b>
Oracle	An Oracle-specific kludge:  <pre>INSERT INTO tablename SELECT 0,'foo' FROM DUAL UNION ALL SELECT 1,'bar' FROM DUAL UNION ALL SELECT 2,'baz' FROM DUAL</pre>
If i	O TODO

## The BOOLEAN type

Standard	<p>The BOOLEAN type is optional (has feature ID T031), which is a bit surprising for such a basic type. However, it seems that endless discussions of how NULL is to be interpreted for a boolean value is holding BOOLEAN from becoming a core type.</p> <p>The standard says that a BOOLEAN may be one of the following literals:</p> <ul style="list-style-type: none"> <li>• TRUE</li> <li>• FALSE</li> <li>• UNKNOWN or NULL (unless prohibited by a NOT NULL constraint)</li> </ul> <p>The DBMS may interpret NULL as equivalent to UNKNOWN. It is unclear from the specification if the DBMS <i>must</i> support UNKNOWN, NULL or both as boolean literals. In this author's opinion, you should forget about the UNKNOWN literal in order to simplify the situation and let the normal SQL three-way logic apply.</p> <p>It's defined that TRUE &gt; FALSE (true larger than false).</p>
PostgreSQL	<p>Follows the standard.</p> <p>Accepts NULL as a boolean literal; doesn't accept UNKNOWN as a boolean literal.</p> <p>DOCUMENTATION</p>
DB2	<p>Doesn't support the BOOLEAN type.</p> <p>Judging from various JDBC-documentation, it seems that IBM recommends a CHAR(1) field constrained to values '0' and '1' (and perhaps NULL) as the way to store boolean values.</p>
MSSQL	<p>Doesn't support the BOOLEAN type.</p> <p>Possible alternative type: the BIT type which may have 0 or 1 (or NULL) as value. If you insert an integer value other than these into a field of type BIT, then the inserted value will silently be converted to 1.</p> <p>Rudy Limeback has some notes about oddities with the MSSQL BIT type.</p> <p>DOCUMENTATION</p>
MySQL	<p>Offers a non-conforming BOOLEAN type. MySQL's BOOLEAN is one of many aliases to its TINYINT(1) type.</p> <p>(Take care if you use TINYINT(1) and JDBC with MySQL and expect to get non-boolean values from it.)</p> <p>MySQL accepts the literals TRUE and FALSE as aliases to 1 and 0, respectively. However, you may also assign a value of — e.g. — 9 to a column of type BOOLEAN (which is non-conforming).</p> <p>If you use JDBC with MySQL, then BOOLEAN is the preferred type for booleans: MySQL's JDBC-driver implicitly converts between Java's boolean and MySQL's pseudo-BOOLEAN type.</p> <p>Side note: MySQL has a BIT type which may be interesting for people with enormous amounts of boolean-type data.</p> <p>DOCUMENTATION</p>
Oracle	<p>Doesn't support the BOOLEAN type.</p> <p>Judging from various JDBC documentation and a discussion at Ask Tom, it seems that Oracle recommends NUMBER(1) as the way to store boolean values; it's probably wise to constrain such columns to values 0 and 1 (and perhaps NULL).</p>
Informix	On my TODO.

Warning to JDBC users:

According to the JDBC standard, `getBoolean()` must convert a SQL-'value' of NULL to the `false` Java value. To check if the database-value was really NULL, use `wasNull()`.

## The CHAR type

For the following section, I have used this test-SQL to try to illuminate differences (unfortunately, even standard SQL as simple as this has to be adjusted for some products):

Test steps:

```
CREATE TABLE chartest (
    charval1 CHAR(10) NOT NULL,
    charval2 CHAR(10) NOT NULL,
    varcharval VARCHAR(30) NOT NULL
);
```

```

INSERT INTO chartest
VALUES ('aaaaaaaaaaa','aaa','aaa'); -- should raise error
SELECT * FROM chartest; -- should show two rows
DELETE FROM chartest WHERE charval1='aaaaaa';
SELECT * FROM chartest; -- should show one row
SELECT * FROM chartest WHERE charval1=varcharval;
SELECT charval1 || 'X' AS res FROM chartest;
SELECT CHAR_LENGTH(charval1 || charval2) AS res FROM chartest;
SELECT CHAR_LENGTH(charval1) + CHAR_LENGTH(charval2)
AS res
FROM chartest;

```

#### Expected results, after CREATE and INSERTs:

```

SELECT * FROM chartest; -- should show two rows
CHARVAL1  CHARVAL2  VARCHARVAL
===== ===== =====
aaa      aaa      aaa
aaaaaa   aaa      aaa

```

```
DELETE FROM chartest WHERE charval1='aaaaaa';
```

```

SELECT * FROM chartest; -- should show one row
CHARVAL1  CHARVAL2  VARCHARVAL
===== ===== =====
aaa      aaa      aaa

```

```

SELECT * FROM chartest WHERE charval1=varcharval;
CHARVAL1  CHARVAL2  VARCHARVAL
===== ===== =====
aaa      aaa      aaa

```

```

SELECT charval1 || 'X' FROM chartest AS res;
res
=====
aaa      X

```

```

SELECT CHAR_LENGTH(charval1 || charval2) AS res FROM chartest;
res
=====
20

```

```

SELECT character_length(charval1) + character_length(charval2)
AS res
FROM chartest;
res
=====
20

```

#### Actual results.

Standard	<ul style="list-style-type: none"> <li>Return with an exception state if the inserted string is too long, unless the characters exceeding the limit are all spaces.</li> <li>Pad CHAR columns with spaces if the inserted string is shorter than the specified CHAR-length.</li> <li>Pad with trailing spaces as needed when casting or comparing to other string-like values (e.g. VARCHARs).</li> </ul>
PostgreSQL	Stores CHARs in space padded form, but violates the standard by (conceptually) truncating trailing white-space before performing most functions, operators, and comparisons (like the <code>CHARACTER_LENGTH</code> -function and the concatenation( <code>  </code> ) operator).  <a href="#">DOCUMENTATION</a>
DB2	Follows the standard.  <a href="#">DOCUMENTATION</a>
MSSQL	Generally follows standard, but (conceptually) truncates trailing white-space before performing some functions (at least before <code>LEN()</code> )

(It's actually not completely silent, as it issues warnings if values were truncated: If you manually check for warnings, you will know that something bad happened, but not which of the rows are now invalid.)

**Violates the standard by effectively truncating all trailing spaces.**

The documentation states that MySQL truncates trailing spaces when CHAR values are *retrieved*. That may be true, but it seems that truncation even happens before the CHAR values are used as input in functions like CONCAT, CHAR\_LENGTH, etc.

	<small>DOCUMENTATION</small> Oracle follows the standard, with a minor exception: Oracle doesn't remove trailing spaces which exceed the specified CHAR length, but raises an exception.
Informix	<small>DOCUMENTATION</small> On my TODO.

## Date and time

### The TIMESTAMP type

Standard	<p>Part of the Core requirements, feature ID F051-03.            Stores year, month, day, hour, minute, second (with fractional digits).            Extension to Core SQL (feature ID F411): TIMESTAMP WITH TIME ZONE which also stores the time zone.</p> <p>Examples of TIMESTAMP literals:</p> <ul style="list-style-type: none"> <li>● TIMESTAMP '2003-07-29 13:19:30'</li> <li>● TIMESTAMP '2003-07-29 13:19:30.5'</li> </ul> <p>Examples of TIMESTAMP WITH TIME ZONE literals:</p> <ul style="list-style-type: none"> <li>● TIMESTAMP '2003-07-29 13:19:30+02:00'</li> <li>● TIMESTAMP '2003-07-29 13:19:30.5+02:00'</li> </ul> <p>It's strange that TIMESTAMP WITH TIME ZONE literals are not represented as, e.g., <code>TIMESTAMP WITH TIME ZONE '2003-07-29 13:19:30+01:00'</code>, but according to Melton &amp; Simon's book, they aren't.</p>
PostgreSQL	<p>Follows that standard with one exception:            In some cases, <code>TIMESTAMP '2003-08-23 01:02:03 +02:00'</code> is interpreted as a <b>TIMESTAMP WITHOUT TIME ZONE</b> (discarding the '+02:00' part)—not as a <b>TIMESTAMP WITH TIME ZONE</b> value. The standard may be illogical regarding this, but a standard is a standard...</p> <p>Performs good sanity checks on inserted timestamp values; e.g. this will work:</p> <pre>INSERT INTO tablename (columnname) VALUES (TIMESTAMP '2003-02-28 00:05:00')</pre> <p>while this will fail:</p> <pre>INSERT INTO tablename (columnname) VALUES (TIMESTAMP '2003-02-29 00:05:00')</pre> <p><small>DOCUMENTATION</small></p>
DB2	<p>DB2 has the <b>TIMESTAMP</b> data type, but not the extended <b>TIMESTAMP WITH TIME ZONE</b> type.</p> <p>Performs good sanity checks on inserted timestamp values; e.g. this will work:</p> <pre>INSERT INTO tablename (columnname) VALUES ('2003-02-28 00:05:00')</pre> <p>while this will fail:</p> <pre>INSERT INTO tablename (columnname) VALUES ('2003-02-29 00:05:00')</pre> <p><small>DOCUMENTATION</small></p>
MSSQL	<p>Note that MSSQL's choice of words related to date and time is confusing: In MSSQL's vocabulary, <b>datetime</b> is a concrete data type, whereas in the SQL standard, <b>datetime</b> is a general term covering the DATE, TIME and <b>TIMESTAMP</b> types.</p> <p>MSSQL has a strange pseudo-type called <b>TIMESTAMP</b>, but has deprecated it; don't use it in new code.</p> <p>The closest match to the SQL standard's <b>TIMESTAMP</b> type is <b>DATETIME</b>. This type stores the combination of date and time. It has a maximum of three fractional digits for seconds.</p> <p>Performs good sanity checks on inserted timestamp values; e.g. this will work:</p> <pre>INSERT INTO tablename (columnname)</pre>

	<b>DOCUMENTATION</b>
MySQL	<p>No matter what date/time data type chosen in MySQL, storage of fractional seconds and time zones are not supported (the <code>TIME</code> type accepts time literals with fractional seconds, but discards the fractional part when storing the value). You will have to invent your own systems for such information.</p> <p>Note also, that MySQL's choice of words related to date and time is confusing: In MySQL's vocabulary, <code>datetime</code> is a concrete data type, whereas in the SQL standard, <code>datetime</code> is a general term covering the DATE, TIME and TIMESTAMP types.</p> <p>MySQL has a type called <code>TIMESTAMP</code>, but it is quite different from the standard <code>TIMESTAMP</code>: It's a 'magic' data type with side effects in that it's automatically updated to the current date and time if some criteria are fulfilled.</p> <p>MySQL has a type called <code>DATETIME</code>. Like MySQL's <code>TIMESTAMP</code> type, it stores a combination of date and time without fractional seconds. There are no side effects associated with the <code>DATETIME</code> type—which makes it the closest match to the SQL standard's <code>TIMESTAMP</code> type.</p> <p>By default, MySQL's sanity checks with regard to dates and time are (deliberately) poor. For example, MySQL accepts <code>DATETIME</code> values of '2003-02-29 00:05:00' and '2003-01-32 00:00:00'. Such values yield warnings (which you must check for if you want to be warned), but result in a value of zero being stored.</p>
	<b>DOCUMENTATION</b>
Oracle	<p>Follows the standard. Oracle has both the <code>TIMESTAMP</code> and the extended <code>TIMESTAMP WITH TIME ZONE</code> types.</p> <p>A special gotcha applies, though: Oracle forbids columns of type <code>TIMESTAMP WITH TIME ZONE</code> as part of a unique key; this includes primary and foreign keys. Timestamps without time zone (and Oracle's special <code>TIMESTAMP WITH LOCAL TIME ZONE</code>) are accepted.</p> <p>Performs good sanity checks on inserted timestamp values; e.g. this will work:</p> <pre>INSERT INTO tablename (columnname) VALUES (TIMESTAMP'2003-02-28 00:05:00')</pre> <p>while this will fail:</p> <pre>INSERT INTO tablename (columnname) VALUES (TIMESTAMP'2003-02-29 00:05:00')</pre>
	<b>DOCUMENTATION</b>
Informix	On my TODO.

## SQL functions

### CHARACTER\_LENGTH

Standard	<p><code>CHARACTER_LENGTH(argument)</code></p> <p>If the optional feature T061 is implemented, the function may be augmented with an indication of <i>string unit</i>:</p> <p><code>CHARACTER_LENGTH(argument USING string-unit)</code></p> <p><i>string-unit</i> may be <code>UTF8</code>, <code>UTF16</code>, <code>UTF32</code>.</p> <p>Returns <code>NUMERIC</code>. Returns <code>NULL</code> if the input is <code>NULL</code>.</p> <p>Alias: <code>CHAR_LENGTH</code>.</p> <p>The argument may be of type <code>CHAR</code> or <code>VARCHAR</code>.</p> <p>Part of the Core SQL requirements (feature ID E021-04).</p> <p>Related function: <code>OCTET_LENGTH</code>.</p>
PostgreSQL	<p>Follows the standard, providing <code>CHARACTER_LENGTH</code> (and <code>CHAR_LENGTH</code>).</p> <p>Note that PostgreSQL removes trailing (not leading) space from CHAR values before counting. Note also that the behaviour of <code>CHARACTER_LENGTH</code> with regard to CHAR values has changed between versions 7.4 and 8.0 of PostgreSQL.</p>
DB2	<p>Has a <code>CHARACTER_LENGTH</code> function, but it's non-compliant because it requires indication of <i>string unit</i>, and db2's string units are different from the standard's.</p> <p>Provides the <code>LENGTH</code> function for those who don't want to think about string units, but the <code>LENGTH</code> function may return wrong results in UTF-8 databases.</p> <p>Note that CHAR values are space-padded (like the standard says they should be), so the length of '<code>HEY </code>' is 5. Consider using <code>LENGTH(TRIM(foo))</code> if you want the length without trailing spaces.</p>

Note that MSSQL's `LEN`-function removes trailing (not leading) spaces from CHAR values before counting; MSSQL's `DATALENGTH` doesn't discard spaces.

#### DOCUMENTATION: LEN and DATALENGTH

MySQL	<p>Provides <code>CHARACTER_LENGTH</code>. Aliases: <code>CHAR_LENGTH</code>, <code>LENGTH</code>. Note that MySQL removes trailing (not leading) spaces from CHAR values before counting.</p> <p>DOCUMENTATION</p>
Oracle	<p>Doesn't have <code>CHARACTER_LENGTH</code>. Provides the <code>LENGTH</code> function instead.  Behaves in strange ways if the input is the empty string or NULL, because of Oracle's non-standard NULL handling (it considers NULL and the empty string identical 'values').  Note that CHAR values are space-padded (like the standard says they should be), so the length of '<code>HEY </code>' is 5. Consider using <code>LENGTH(TRIM(TRAILING FROM foo))</code> if you want the length without leading/trailing spaces.</p> <p>DOCUMENTATION</p>
Informix	On my TODO.

## SUBSTRING

Standard	<p>The standard defines two variants of the SUBSTRING function:</p> <ol style="list-style-type: none"> <li>To comply with Core SQL (Feature E021-06), the DBMS must support an '<b>ordinary</b>' SUBSTRING function which extracts characters from a string:  <code>SUBSTRING(input FROM start-position [FOR length])</code>            Strings start at position 1. The <code>start-position</code> argument is a numeric value, as is the optional <code>length</code>-argument. If no <code>length</code> parameter is indicated, <code>length</code> becomes <i>infinite</i>             (The standard specifies an extra optional argument—<code>USING x</code>—that has to do with <i>Universal Character Sets</i>, e.g. Unicode. <code>x</code> may be one of OCTETS or CHARACTERS.)             The result is NULL if any of the arguments is NULL.</li> </ol> <p>Some cases of out-of-range values for <code>start-position</code> and <code>length</code> are allowed. Examples:</p> <ul style="list-style-type: none"> <li><code>SUBSTRING('12345' FROM 6)</code> yields the empty string.</li> <li>A <code>start-position</code> less than 1 effectively sets <code>start-position</code> to 1 and reduces the value of <code>length</code> by <math>1+abs(start-position)</math>. I.e., if <code>start-position</code> is -3 and <code>length</code> is 6, then the <code>length</code> value becomes 2.</li> </ul> <p>Another way to put it is that when <code>start-position</code> is negative, a bunch of arbitrary/blank characters are prepended to the input-value. <math>bunch=1-start-position</math>.</p> <p>For an exact definition: see item three in the "General Rules" part of section 6.29 in the standard.</p> <ol style="list-style-type: none"> <li>The DBMS may optionally offer a <b>regular expression</b> variant (Feature T581) of SUBSTRING:  <code>SUBSTRING(input SIMILAR pattern ESCAPE escape-char)</code>            Pattern deserves some explanation. It's a string which needs to consist of three parts: A part matching <i>b</i> before the wanted sub-string, the wanted substring, and a part matching <i>a</i>fter the wanted substring.            The parts must be separated by a combination of the indicated <code>escape-char</code> (escape-character) and a double-quote ("). Example:  <code>SUBSTRING('abc' SIMILAR 'a#"b#"c' ESCAPE '#')</code>            should yield  <code>b</code>            The pattern description rules in SQL don't completely resemble POSIX regular expressions, as far as I can see.</li> </ol>
PostgreSQL	<p>PostgreSQL provides three SUBSTRING flavors:</p> <ul style="list-style-type: none"> <li>Ordinary SUBSTRING: As the standard's ordinary SUBSTRING variant.</li> <li>POSIX regular expression SUBSTRING: Syntax is  <code>SUBSTRING(input FROM pattern-string)</code>            Pattern rules are of the POSIX variant. Returns NULL when pattern doesn't match.</li> <li>Sort-of SQL-style regular expression SUBSTRING: Syntax is  <code>SUBSTRING(input FROM pattern-string FOR escape-char)</code>            Pattern-rules are supposed to match the SQL-standard's rules, although my tests sometimes suggest otherwise (hasn't been reported as bugs because I'm not completely sure how SQL's regex-rules are supposed to be</li> </ul>

	<p>Provides (since version 9) the <code>SUBSTRING</code> function, but requires you to indicate string unit by appending "<code>USING unit</code>". The unit identifier may be <code>CODEUNITS16</code>, <code>CODEUNITS32</code>, or <code>OCTETS</code>. <code>CODEUNITS16/CODEUNITS32</code> seem non-standard. The standard's <code>CHARACTERS</code> unit isn't supported by DB2.</p> <p><b>Example:</b></p> <pre>SELECT SUBSTRING(somecolumn FROM 3 USING OCTETS) FROM sometable SELECT SUBSTRING(somecolumn FROM 3 FOR 2 USING OCTETS) FROM sometable</pre> <p>For old DB2 versions, use the non-standard <code>SUBSTR</code> function.</p> <p>DB2 doesn't provide any built-in regular expression facilities at all (but you may manually add PCRE capabilities).</p> <p>DOCUMENTATION: <a href="#">SUBSTRING</a> and <a href="#">SUBSTR</a></p>
MSSQL	<p>MSSQL has a <code>SUBSTRING</code> function, but its syntax differs from that of the standard. The syntax is:</p> <pre>SUBSTRING(input, start, length)</pre> <p>where <code>start</code> is an integer specifying the beginning of the string, and <code>length</code> is a non-negative integer indicating how many characters to return.</p> <p>MSSQL has no regular expression functionality.</p> <p>DOCUMENTATION</p>
MySQL	<p>MySQL supports the standard's ordinary <code>SUBSTRING</code> function, with some twists (see below). No regular expression based substring extraction is supported.</p> <p>MySQL breaks the standard when negative values are used as either start-position or length:</p> <ul style="list-style-type: none"> <li>According to the standard, <code>SUBSTRING('abc' FROM -2 FOR 4)</code> should yield '<code>a</code>'; in MySQL, the result is '<code>bc</code>'.</li> <li>According to the standard, <code>SUBSTRING('abc' FROM 2 FOR -4)</code> should yield an error; MySQL returns an empty string.</li> </ul> <p>DOCUMENTATION</p>
Oracle	<p>Doesn't provide the standard <code>SUBSTRING</code> function. Provides <code>SUBSTR(input,start-pos[,length])</code> instead (i.e. <code>length</code> is optional).</p> <p>Oracle provides a number of <code>SUBSTR</code>-variants (<code>SUBSTRB</code>, <code>SUBSTRC</code>, <code>SUBSTR2</code>, <code>SUBSTR4</code>, same syntax as for <code>SUBSTR</code>), mainly for handling various kinds of non-latin-only string-types.</p> <p>Oracle doesn't have support for string-extraction with the special SQL-style regular expressions. Instead, it has the <code>REGEXP_SUBSTR</code> function which offers string extraction, using POSIX-style regular expression pattern matching.</p> <p>DOCUMENTATION: <a href="#">SUBSTR</a> and <a href="#">REGEXP_SUBSTR</a>.</p>
Informix	On my TODO.

Note: If you find yourself using `SUBSTRING` in a WHERE-expression, then consider if `LIKE` could be used instead: The use of `LIKE` will typically make your DBMS try to use an index, whereas it will typically not try to do so in connection with functions.

## REPLACE

`REPLACE` means a string-function which searches a source string (haystack) for occurrences of a string to be replaced (needle) and replaces it with a new string (replacement).

Standard	<p>Not mentioned. May be obtained through a combination of other functions (have a look at the <code>OVERLAY</code>, <code>POSITION</code> and <code>CHARACTER_LENGTH</code> functions).</p> <p>A <i>de facto</i> standard seems to have emerged with regard to <code>REPLACE</code>:</p> <pre>REPLACE (haystack:string,needle:string,replacement:string)</pre> <p>which means 'replace <code>needle</code> with <code>replacement</code> in the string <code>haystack</code>'. Replacement is done case-<b>sensitively</b> unless otherwise stated.</p> <p>The <code>REPLACE</code> function may be handy for correcting spelling errors (and other situations):</p> <pre>UPDATE tablename SET fullname=REPLACE(fullname,'Jeo ','Joe ')</pre>
PostgreSQL	Follows <i>de facto</i> standard.
	DOCUMENTATION
DB2	Follows <i>de facto</i> standard.
	DOCUMENTATION
MSSQL	Follows <i>de facto</i> standard with the exception that MSSQL by default works case <b>insensitively</b>

	Note that the <code>REPLACE</code> -function is different from MySQL's non-standard <code>REPLACE INTO</code> expression. DOCUMENTATION
Oracle	Follows <i>de facto</i> standard. DOCUMENTATION
Informix	On my TODO.

Note 1:

In this author's opinion, it's confusing that most (if not all) string-related functions in MySQL work case **sensitively**, while MySQL's default behaviour is to work case **insensitively** in plain WHERE-clauses involving string comparisons.

## TRIM

Standard	<p>Core SQL feature ID E021-09: <code>TRIM(where characters FROM string_to_be_trimmed)</code></p> <p>where may be one of LEADING, TRAILING or BOTH—or omitted which implies BOTH.</p> <p>characters indicates what character(s) to remove from the head and/or tail of the string. It may be omitted which implies the value '' (space character).</p> <p>In other words, the shortest form is <code>TRIM(string_to_be_trimmed)</code> which in effect means <code>TRIM(BOTH ' ' FROM string_to_be_trimmed)</code>.</p> <p>Trimming NULL returns NULL.</p>
PostgreSQL	Follows the standard. DOCUMENTATION
DB2	Follows the standard, (since version 9.1)  In db2 versions lower than 9.1, you only have: <code>LTRIM(string_to_be_trimmed)</code> and <code>RTRIM(string_to_be_trimmed)</code>  DOCUMENTATION.
MSSQL	Doesn't support the standard TRIM function.  Provides <code>LTRIM(string_to_be_trimmed)</code> and <code>RTRIM(string_to_be_trimmed)</code>  DOCUMENTATION: LTRIM and RTRIM
MySQL	Follows the standard. DOCUMENTATION
Oracle	Follows the standard with two exceptions: <ul style="list-style-type: none"> <li>Oracle doesn't allow you to trim multiple characters. I.e., <code>TRIM('**' FROM foo)</code> is illegal in Oracle.</li> <li>Due to Oracle's non-standard NULL-handling, you may get strange results of trimming NULL or the empty string.</li> </ul> DOCUMENTATION
Informix	On my TODO.

## LOCALTIMESTAMP

It's often important to get the value of current date and time. Below are the functions used to do that in the different implementations.

Standard	<p>The current timestamp (without time zone) is retrieved with the LOCALTIMESTAMP function which may be used as:</p> <pre>SELECT LOCALTIMESTAMP ...</pre> <p>or</p> <pre>SELECT LOCALTIMESTAMP(precision) ...</pre> <p>Note that "SELECT LOCALTIMESTAMP() ..." is illegal: If you don't care about the precision, then you must not use any parenthesis.</p> <p>If the DBMS t th ti f t (f t ID F411) th it t l id th f ti</p>
----------	--

PostgreSQL	Follows the standard.
DB2	<p>DOCUMENTATION</p> <p>Doesn't have the LOCALTIMESTAMP function.</p> <p>Instead, it provides a special, magic value ('special register' in IBM language), CURRENT_TIMESTAMP (alias to 'CURRENT TIMESTAMP' which may be used as though it were a function without arguments. However, since DB2 doesn't provide TIMESTAMP WITH TIME ZONE support, the availability of CURRENT_TIMESTAMP could be said to be against the standard—at least confusing.</p> <p>DOCUMENTATION</p>
MSSQL	<p>Doesn't have the LOCALTIMESTAMP function.</p> <p>Instead, it has CURRENT_TIMESTAMP which—however—doesn't return a value of TIMESTAMP WITH TIME ZONE, but rather a value of MSSQL's DATETIME type (which doesn't contain time zone information).</p> <p>DOCUMENTATION</p>
MySQL	<p>Follows the standard.</p> <p>DOCUMENTATION</p>
Oracle	Follows the standard.
Informix	On my TODO.

## Concatenation

Standard	<p>Core feature ID E021-07:</p> <p>Concatenating two strings is done with the <code>  </code> operator:</p> <pre>string1    string2</pre> <p>If at least one operand is NULL, then the result is NULL.</p> <p>It's unclear to me if the DBMS is allowed to try to automatically cast the operands to concatenation-compatible types.</p>
PostgreSQL	<p>Follows the standard.</p> <p>Automatically casts the concatenated values into types compatible with concatenation. If an operand is NULL then the result is NULL.</p> <p>DOCUMENTATION</p>
DB2	<p>Follows the standard, partly.</p> <p>Does not automatically cast concatenated values into compatible types.</p> <p>DOCUMENTATION</p>
MSSQL	<p>Breaks the standard by using the <code>+</code> operator instead of <code>  </code>.</p> <p>Does not automatically cast operands to compatible types. If an operand is NULL, then the result is NULL.</p> <p>DOCUMENTATION</p>
MySQL	<p>Badly breaks the standard by redefining <code>  </code> to mean OR.</p> <p>Offers instead a function, <code>CONCAT(string, string)</code>, which accepts two or more arguments.</p> <p>Automatically casts values into types which can be concatenated. If an operand is NULL, then the result is NULL.</p> <p>DOCUMENTATION</p>
Oracle	<p>Follows the standard, partly.</p> <p>Automatically casts values into types which can be concatenated.</p> <p>As Oracle interprets NULL as the empty string, it doesn't return NULL if an operand is NULL.</p> <p>DOCUMENTATION</p>
Informix	<p>Follows the standard.</p> <p>Automatically casts numeric data into character data, if needed. If an operand is NULL then the result is NULL.</p> <p>DOCUMENTATION</p>

## The UNIQUE constraint

Standard	<p>As the constraint name indicates, a (set of) column(s) with a UNIQUE constraint may only contain unique (combinations of) values.</p> <p>A column—or a set of columns—which is subject to a UNIQUE constraint must also be subject to a <i>not NULL</i> constraint, unless the DBMS implements an optional "NULLs allowed" feature (Feature ID 591). The optional feature adds some additional characteristics to the UNIQUE constraint:</p> <ol style="list-style-type: none"> <li>1. Columns involved in a UNIQUE constraint <i>may</i> also have NOT NULL constraints, but they do not have to.</li> <li>2. If columns with UNIQUE constraints do <i>not</i> also have NOT NULL constraints, then the columns may contain <i>any</i> number of NULL-'values'. (Logical consequence of the fact that <math>\text{NULL} \leftrightarrow \text{NULL}</math>.)</li> </ol> <p>In the standard-parlance, the constraint is satisfied, if</p> <p style="padding-left: 40px;"><i>there are no two rows in [the relation] such that the value of each column in one row is non-null and is not distinct from the value of the corresponding column in the other row</i></p>
PostgreSQL	<p>Follows the standard, including the optional NULLs allowed feature.</p> <p>DOCUMENTATION</p>
DB2	<p>Follows the non-optional parts of the UNIQUE-constraint. Doesn't implement the optional NULLs allowed feature.</p> <p>DOCUMENTATION (see the <i>unique-constraint</i> section of the page).</p>
MSSQL	<p>Follows the standard—with a twist:</p> <p>MSSQL offers the NULLs allowed feature, but allows <i>at most</i> one instance of a NULL-'value', if NULLs are allowed; i.e. breaks characteristic 2 in the above description of the standard.</p> <p>DOCUMENTATION</p>
MySQL	<p>Follows the standard, including the optional NULLs allowed feature.</p>
Oracle	<p>Follows the standard—with a twist regarding multiple-column UNIQUE-constraints:</p> <p>The optional NULLs allowed feature is implemented: If the UNIQUE-constraint is imposed on a <i>single</i> column, then the column may contain any number of NULLs (as expected from characteristic 2 in the above description of the standard). However, if the UNIQUE-constraint is specified for <i>multiple</i> columns, then Oracle sees the constraint as violated if any two rows</p> <ul style="list-style-type: none"> <li>• contain at least one NULL in a column affected by the constraint</li> <li>• identical, non-NUL values in the rest of the columns affected by the constraint</li> </ul> <p>DOCUMENTATION</p>
Informix	On my TODO.

## Mixture of type and operations

### Automatic key generation

It's sometimes handy to have the DBMS handle generation of keys. The DBMSes offer various means for this. Note, however, that some database authorities warn against—at least some variants of—auto-generated keys; this is a classic database discourse.

Standard	<p>The standard specifies a column attribute of: GENERATED ... AS IDENTITY (non-core feature ID T174+T175).</p> <p>When creating a table, an IDENTITY clause may be declared for certain types of columns (INTEGER being one):</p> <pre>CREATE TABLE tablename (     tablename_id INTEGER GENERATED ALWAYS AS IDENTITY     ... )</pre> <p>or</p> <pre>CREATE TABLE tablename (     tablename_id INTEGER GENERATED BY DEFAULT AS IDENTITY     ... )</pre> <p>The column with the IDENTITY attribute will be given values in increasing order possibly with 'holes' ( 3 4 7 )</p>
----------	---

The examples differ in their 'ALWAYS' vs. 'BY DEFAULT' clauses:

- When ALWAYS is specified, the user cannot specify a value for the column which means that the DBMS can guarantee successful insertion of a unique value on each table insert.
- When BY DEFAULT is specified, the user may manually specify what value to put in the identity field of a row. The flip side is that the DBMS cannot guarantee that this will work.

The standard specifies several extended options which may be declared for a generated IDENTITY column.

**PostgreSQL** PostgreSQL doesn't support the standard's IDENTITY attribute.

PostgreSQL's best offering for a column with auto-generated values is to declare a column of 'type' SERIAL:

```
CREATE TABLE tablename (
    tablename_id SERIAL,
    ...
)
```

'SERIAL' is a short-hand for creating a sequence and using that sequence to create unique integers for a column. If the table is dropped, PostgreSQL will drop the sequence which was created as a side-effect of using the SERIAL type.

As a user may manually insert or update a value in a column created as SERIAL, this comes closest to the standard's GENERATED BY DEFAULT AS IDENTITY variant.

If you want semantics like the standard's GENERATED ALWAYS AS IDENTITY, then SERIAL will not do it; instead you need to:

1. Create a sequence for the table (assuming that the table is called *footab*, having a integer column called *id*):

```
CREATE SEQUENCE footab_id_seq
```

2. Add the PL/pgSQL language to the database, in case it doesn't already exist (extra additions don't hurt):

```
CREATE LANGUAGE plpgsql
```

3. Create a function to be called by a trigger when *footab* is changed:

```
CREATE OR REPLACE FUNCTION protect_footab_id() RETURNS TRIGGER AS $$

BEGIN

    IF tg_op = 'INSERT' THEN
        IF new.id IS NOT NULL THEN
            RAISE EXCEPTION 'setting ID manually not allowed (%)', new.id;
        END IF;
        new.id = NEXTVAL('footab_id_seq');
    ELSE
        IF new.id IS DISTINCT FROM old.id THEN
            RAISE EXCEPTION 'changing ID is not allowed (% to %)', old.id, new.id;
        END IF;
    END IF;
    RETURN NEW;
END;

$$ LANGUAGE PLPGSQL
```

4. Create the trigger, calling the above function:

```
CREATE TRIGGER protect_footab_id
    BEFORE INSERT OR UPDATE ON footab
    FOR EACH ROW EXECUTE PROCEDURE protect_footab_id()
```

Another option is to add the WITH OIDS clause when creating a table. Object identifiers (OIDs) will then be added to a special *oid* column which is hidden by default, i.e. isn't included in SELECT \* FROM ... result sets). The *oid* column can be revealed by explicitly adding it to the SELECT-list, and it can be referred to in WHERE clauses. OIDs cannot be assigned by the user, so the semantics of OIDs resemble the standard's GENERATED ALWAYS AS IDENTITY attribute.

DOCUMENTATION: The SERIAL and OIDs types.

**DB2** Follows standard, albeit with some restrictions on how identity columns may (not) be added to an existing table, etc.  
DOCUMENTATION: CREATE TABLE syntax and description of identity columns.

**MSSQL** MSSQL offers IDENTITY as a column property, but with a different syntax than the standard's specification. An example of creating a table with an IDENTITY column:

```
CREATE TABLE tablename (
    tablename_id INT IDENTITY PRIMARY KEY,
    ...
)
```

I.e., MSSQL's `IDENTITY` type is closest to the standard's `GENERATED ... ALWAYS AS IDENTITY variant.`

DOCUMENTATION: The `IDENTITY` property and `SET IDENTITY_INSERT`.

## MySQL

MySQL doesn't support the standard's `IDENTITY` attribute.

As an alternative, an integer column may be assigned the non-standard `AUTO_INCREMENT` attribute:

```
CREATE TABLE tablename (
    tablename_id INTEGER AUTO_INCREMENT PRIMARY KEY,
    ...
)
```

Columns with the `AUTO_INCREMENT` attribute will—under certain conditions—automatically be assigned a value of <largest value in column>+<at least 1>. Look in MySQL's documentation for the (rather extensive) details.

A table can have at most one column with the `AUTO_INCREMENT` attribute; that column must be indexed (it doesn't have to be a primary key, as in the example SQL above) and cannot have a `DEFAULT` value attribute.

It's probably not too far fetched to think of MySQL's `AUTO_INCREMENT` feature as this equivalence:

MySQL:

```
CREATE TABLE tablename (
    columnname INTEGER AUTO_INCREMENT PRIMARY KEY
    ...
)
```

Standard SQL:

```
CREATE TABLE tablename (
    columnname INTEGER DEFAULT some_func() PRIMARY KEY
    ...
)
```

where `some_func()` is a function which finds 1 plus the currently largest value of `columnname`.

The nice thing about this approach is that the automatic value insertion should never fail, even though some of the column's values might have been manually set—i.e. the combined advantages of the standard's `ALWAYS` and `BY DEFAULT` variants.

The draw back is that it might result in more house-keeping: The system may need extra table locks when performing row updates/insertions to protect against ghost updates in concurrent transactions—thus slowing down the system in case of many concurrent updates/insertions.

DOCUMENTATION

## Oracle

Oracle doesn't support the standard's `IDENTITY` attribute.

If you want an auto-incrementing column in Oracle, then create a sequence and use that sequence in a trigger associated to the table. Example: For the table `mytable`, you want the `mytable_id` column to be of integer type, with an auto-incrementing values:

```
CREATE TABLE mytable (
    mytable_id INTEGER PRIMARY KEY,
    ... -- (other columns)
);

CREATE SEQUENCE mytable_seq;

CREATE TRIGGER mytable_seq_trigger
BEFORE INSERT ON mytable FOR EACH ROW
BEGIN
    IF (:new.mytable_id IS NULL) THEN
        SELECT mytable_seq.nextval INTO :new.mytable_id
        FROM DUAL;
    END IF;
END;
/
```

This will create an auto-incrementing column resembling the `GENERATED BY DEFAULT` variant from the standard. If an column resembling the `GENERATED ALWAYS` variant is needed, then the trigger should be extended to raise an exception if the user tries to insert a non-NULL value, and a trigger preventing UPDATEs of the relevant column should be added.

Informix	On my TODO.
Note: IBM has a page comparing IDENTITY columns and sequences.	
<h2>Bulk operations</h2>	
<h3>TRUNCATE TABLE</h3>	
	<p>Often, it's useful to be able to remove all rows from a large table in a quick way. And often, <code>DELETE</code> isn't as quick as you'd like it to be. So several DBMSes implement a <code>TRUNCATE</code> operation. Typically, truncating means that deletion isn't associated with triggers which may exist for the table, and typically, truncating involves little (if any) transaction log activity.</p>
Standard	<p>The SQL standard defines the <code>TRUNCATE TABLE tablename</code> statement (optional feature ID F200, new in SQL:2008) as: Delete all rows of a base table without causing any triggered action.</p> <p>Unfortunately, the standard doesn't specify</p> <ol style="list-style-type: none"> <li>1. whether <code>TRUNCATE TABLE</code> should be allowed in a transaction involving other statements, or not</li> <li>2. whether <code>TRUNCATE TABLE</code> should imply an immediate <code>COMMIT</code>, or not</li> </ol>
PostgreSQL	<p>Follows the standard.</p> <p>In PostgreSQL, <code>TRUNCATE TABLE</code> is <i>allowed in a transaction</i> involving other operations, and <code>TRUNCATE TABLE</code> does <i>not imply</i> an immediate <code>COMMIT</code> operation.</p> <p>See the documentation for variations and restrictions. Most importantly, you need to have be owner of the table to be truncated (or work as a superuser); alternatively, you need to have <code>TRUNCATE</code> privilege on the table. Note also the nice—but potentially dangerous—<code>CASCADE</code> modifier which may be useful for emptying related tables.</p> <p>DOCUMENTATION</p>
DB2	<p>Almost follows the standard (since version 9.7)</p> <p>DB2 requires that the <code>IMMEDIATE</code> keyword be added to the ordinary <code>TRUNCATE TABLE</code> statement, e.g.:</p> <pre>TRUNCATE TABLE someschema.sometable IMMEDIATE</pre> <p><code>TRUNCATE TABLE</code> must be the first statement in a transaction. A transaction starting with <code>TRUNCATE TABLE</code> may include other statements, but if the transaction is rolled back, the <code>TRUNCATE TABLE</code> operation is not undone.</p> <p>DB2's <code>TRUNCATE TABLE</code> operation has a number of optional arguments, see the documentation for more on this; especially, the <code>REUSE STORAGE</code> argument may be important for ad-hoc DBA tasks.</p> <p>In DB2 versions &lt; 9.7, you may abuse the <code>IMPORT</code> statement. Unfortunately, you need to know which operating system the command is executed from for this to work:</p> <ul style="list-style-type: none"> <li>• On unix-like systems:       <pre>IMPORT FROM /dev/null OF DEL REPLACE INTO tablename</pre> </li> <li>• On Windows:       <pre>IMPORT FROM NUL OF DEL REPLACE INTO tablename</pre> </li> </ul> <p><code>IMPORT</code> cannot be abused in all contexts. E.g., when working with dynamic SQL (from Java/.NET/PHP/...—not using the <code>db2</code> command line processor), you need to wrap the <code>IMPORT</code> command in a call to <code>ADMIN_CMD</code>, e.g.:</p> <pre>CALL ADMIN_CMD('IMPORT FROM /dev/null OF DEL REPLACE INTO tablename')</pre> <p><code>IMPORT</code> seems to be <i>allowed in a transaction</i> involving other operations, however it implies an immediate <code>COMMIT</code> operation.</p> <p>The <code>ALTER TABLE</code> command may also be abused to quickly empty a table, but it requires more privileges, and may cause trouble with rollforward recovery.</p> <p>DOCUMENTATION:</p> <ul style="list-style-type: none"> <li>• <code>TRUNCATE TABLE</code></li> <li>• <code>IMPORT</code></li> <li>• <code>IMPORT</code> through <code>ADMIN_CMD</code></li> </ul>
MSSQL	<p>Follows the standard.</p> <p>In MSSQL, <code>TRUNCATE TABLE</code> is <i>allowed in a transaction</i> involving other operations, and <code>TRUNCATE TABLE</code> does <i>not imply</i> an immediate <code>COMMIT</code> operation.</p> <p>You need to have at least <code>ALTER</code>-permission on the table to be truncated.</p>

potentially slow and trigger-invoking). Its behaviour depends on which *storage engine* the table is managed by.

When using InnoDB (transaction safe) tables, `TRUNCATE TABLE` is *allowed in a transaction* involving other operations, how ever `TRUNCATE TABLE` *implies* an immediate `COMMIT` operation.

#### DOCUMENTATION

Oracle	<p>Follows the standard.</p> <p>Note, that the <code>TRUNCATE TABLE</code> <i>implicitly</i> commits the current transaction.</p> <p>You may find that <code>TRUNCATE TABLE</code> isn't nearly as quick as expected; in this case, consider using <code>TRUNCATE TABLE tablename REUSE STORAGE</code> instead.</p> <p>Needed privileges—Quoting from the documentation:  <i>...the table or cluster must be in your schema or you must have DROP ANY TABLE system privilege.</i></p>
Informix	On my TODO.

## Command line procedures / metadata

The following are not necessarily SQL operations, but rather a description of how different operations are performed in the command line interface provided by each product.

The shape of the command line interfaces in the commercial products is depressing. Vendors, please do something about it: Not all database developers like to use slow GUIs for technical stuff. And sometimes, DBMS work is performed over slow Internet lines which makes a decent command line interface vital.

Fortunately, a tool like HenPlus exists. It can be a pain to install, but once working, it's nice to work with.

### Starting the command line interface

Standard	Not defined.
PostgreSQL	<p>Run:</p> <pre>psql</pre> <p>which should be in the PATH in any sensible installation.</p> <p>PostgreSQL's command line interface is very user friendly. It has command history (press arrow-up for previous commands) and a fairly well-working command completion feature.</p>
DB2	<p>Run:</p> <pre>db2 -t</pre> <p>(The <code>-t</code> argument tells the command line processor to a semicolon as statement terminator instead of the default (newline). This allows for multi-line SQL statements.)</p> <p>The <code>db2</code> binary may not be in your PATH or may be missing vital environment variables (which is one of the stupid parts of DB2's installation procedure: It doesn't offer to set up a proper global DB2 environment for the users on the server) and you may have to include the <code>db2profile</code> file (situated in the <code>sqllib</code> directory in the home directory of the special DB2 instance user) into your shell.</p> <p>E.g. on my Linux system, I've added the following line to my <code>.bash_profile</code> in order to get a shell with proper DB2 environment when logging in:</p> <pre>./home/db2inst1/sqllib/db2profile</pre> <p>The 'utility' doesn't seem to have anything resembling useful command history or command completion. Fortunately, queries may be sent to the <code>db2</code> 'utility' in a non-interactive way like this:</p> <pre>db2 "SELECT a_column FROM a_table"</pre> <p>This allows you to make use of your shell's command history handling.</p> <p>DB2 also has a 'utility' called <code>db2batch</code> which some might find a bit nicer to work with.</p>
MSSQL	<p>The command line interface is started by running <code>sqlcmd</code></p> <p><code>sqlcmd</code> is not nice to work with. It's bad at formatting result sets. It doesn't have command line completion. You have to say <code>go</code> after your commands. A positive thing about <code>sqlcmd</code>: It has command history, so you may press arrow-up for previous commands in the current <code>sqlcmd</code> session.</p>

operating system, except it doesn't seem to support Kerberos, so you need to log into the database using a database-account (not a Windows account).

## DOCUMENTATION

MySQL	<p>Run:</p> <pre>mysql</pre> <p>If you need help on the optional command line options, see the man page.</p> <p>On platforms like Linux and FreeBSD (which have decent readline-capabilities), MySQL's command line interface is simply great; not much else to say. MySQL's command line interface is said to be rather poor on Windows, though.</p>
Oracle	<p>Run:</p> <pre>sqlplus</pre> <p>sqlplus lacks command completion, and has very limited built-in command history handling.</p> <p>DOCUMENTATION</p> <p>A unique feature of Oracle is that a web-based administration interface is provided, as a supplement to the local administration software. The URL to the interface is typically <a href="https://hostname:1158/em/">https://hostname:1158/em/</a></p>
Informix	<p>Informix' command line utility is called dbaccess. If run without arguments, it starts a menu system. If you simply want to shoot SQL statements off to the database, another form is more convenient, at least on unix:</p> <pre>echo 'SELECT foo FROM bar'   dbaccess <b>databasename</b></pre> <p>DOCUMENTATION</p>

**Getting a list of databases**

Standard	Not specified, as far as I know. (By the way: The SQL standard doesn't have the concept of a <i>database</i> as a container of schemas; instead, the standard specifies that schemas are contained in a <i>catalog</i> .)
PostgreSQL	<p>Using SQL: <code>SELECT datname FROM pg_catalog.pg_database</code></p> <p>When working in the <code>psql</code> command line interface: <code>\l</code> or <code>\l+</code></p> <p>Alternative (when working from the terminal, not in <code>psql</code>): <code>psql --list</code></p> <p>DOCUMENTATION: The <code>psql</code> tool, the <code>pg_database</code> catalog.</p>
DB2	<p>Offers the <code>LIST DATABASE DIRECTORY</code> command, but only when working in the <code>db2</code> command line processor (i.e. not when working from <code>db2batch</code>); this command's output is human readable, but sub-optimal as machine readable format.</p> <p>DOCUMENTATION</p>
MSSQL	<pre>EXEC SP_HELPDB</pre> <p>DOCUMENTATION</p>
MySQL	<pre>SHOW DATABASES</pre> <p>DOCUMENTATION</p>
Oracle	<p>In Oracle, there is a one-to-one relationship between <i>databases</i> and <i>instances</i> (unless you work with a clustered Oracle system). You can get a list of instances; the way to do it depends on the operating system which Oracle is running on:</p> <ul style="list-style-type: none"> <li>On unix-like systems: Look in the <code>/etc/oratab</code> file.</li> <li>On Windows: Start Windows' Services management console and look for services with names starting with <code>OracleServicexxxx</code>. Each <code>xxxx</code> is the name (AKA <i>SID</i>) of an instance.</li> </ul> <p>Documentation: ORATAB</p>
Informix	<p>Connect to the <code>sysmaster</code> database (all users are allowed to do this) and run:</p> <pre>SELECT name FROM sysmaster:sysdatabases</pre> <p>DOCUMENTATION</p>

**Getting a list of schemas**

Standard	<code>SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA</code>
PostgreSQL	In the command line interface: <code>\dn</code> or <code>\dn+</code> (for more details).

- The `psql` tool
- The schemata `INFORMATION_SCHEMA` view

DB2	<pre>SELECT schemaname FROM syscat.schemata</pre> <p>DOCUMENTATION</p>
MSSQL	<p>Follows the standard.</p> <p>DOCUMENTATION</p>
MySQL	<p>MySQL doesn't support schemas.</p>
Oracle	<p>Oracle has a peculiar approach to schemas: A schema exists for each and every user. And there cannot be a schema without a corresponding user. Consequently, a way to get a list of schemas in Oracle is to query the <code>ALL_USERS</code> dictionary view :</p> <pre>SELECT username FROM all_users</pre> <p>DOCUMENTATION</p>
Informix	<p>Informix' concept of schemas is closely related to user names, so—somewhat surprisingly—the query is:</p> <pre>SELECT UNIQUE owner FROM systables WHERE tabid&gt;99</pre> <p>DOCUMENTATION</p>

## Getting a list of tables

Standard	<p>Part 11 of the SQL standard specifies the <code>INFORMATION_SCHEMA</code> schema which must be part of all database catalogues. The schema may be used like this:</p> <pre>SELECT * FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_TYPE='BASE TABLE'</pre> <p>or (often more relevant):</p> <pre>SELECT * FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_TYPE='BASE TABLE'     AND TABLE_SCHEMA='SCHEMA-NAME'</pre> <p>See a warning about potential case sensitivity problems below.</p>
PostgreSQL	<p>Follows the standard, except for some gotchas mentioned below .</p> <p>In command-line context, it's easier to use the following non-SQL command instead of querying the <code>INFORMATION_SCHEMA</code>:</p> <pre>\dt</pre> <p>Documentation: The <code>TABLES INFORMATION_SCHEMA VIEW</code>, the <code>psql TOOL</code>.</p>
DB2	<p>Doesn't provide the standard <code>INFORMATION_SCHEMA</code>. Instead, DB2 offers the <code>SYSCAT</code> schema (catalog) which is somewhat compatible.</p> <p>Offers what is probably a shorthand to some system catalog query:</p> <pre>LIST TABLES</pre> <p>or - if you want to see tables in another schema:</p> <pre>LIST TABLES FOR SCHEMA foo</pre> <p>These commands are only available in the <code>db2</code> command line processor (i.e. not from—e.g.—<code>db2batch</code>).</p> <p>DOCUMENTATION</p>
MSSQL	<p>Follows that standard.</p> <p>Sometimes, the <code>SP_TABLES</code> system stored procedure is easier to use.</p> <p>DOCUMENTATION:</p> <ul style="list-style-type: none"> <li>• The <code>INFORMATION_SCHEMA.TABLES</code> view</li> <li>• <code>sp_tables</code></li> </ul>
MySQL	<p>Follows the standard, except that MySQL doesn't support schemas, so one might say that MySQL's <code>INFORMATION_SCHEMA</code> is really an '<code>INFORMATION_DATABASE</code>' or '<code>INFORMATION_CATALOGUE</code>'.</p> <p>In command-line context, it's easier to use the following non-standard SQL:</p> <pre>SHOW TABLES</pre>

	<ul style="list-style-type: none"> <li>SHOW TABLES</li> </ul>
Oracle	<p>Doesn't provide the standard <code>INFORMATION_SCHEMA</code>. Provides a <i>data dictionary</i> system instead.</p> <p>The quickest way to get a usable list of 'normal' tables in the current schema:</p> <pre>SELECT * FROM tab</pre> <p>Use of the <code>tab</code> dictionary view is officially deprecated, though. The following query takes longer to write, but is more future proof:</p> <pre>SELECT owner  '.'  table_name FROM all_all_tables</pre> <p>(Remember that in Oracle, there is a one-to-one relationship between 'owners' and schemas.)</p> <p>DOCUMENTATION</p>
Informix	<p>Doesn't provide the standard <code>INFORMATION_SCHEMA</code> out of the box. A few of the standard's <code>INFORMATION_SCHEMA</code> views may be added by running a special script, though.</p> <p>Informix offers a set of <i>system catalogs</i> instead. To get a list of tables:</p> <pre>SELECT tablename FROM systables WHERE tabid &gt; 99</pre> <p>The above query will include views and other objects; if you want base tables only:</p> <pre>SELECT tablename FROM systables WHERE tabid &gt; 99 AND tabtype='T'</pre> <p>DOCUMENTATION</p>

#### Warning about a general case sensitivity gotcha

Note that there may be case sensitivity issues involved when using meta-data views like those in the `INFORMATION_SCHEMA`. Generally, the standard states that the name of an identifier (such as table names) are implicitly converted to uppercase, unless double-quotes are used when referring to the identifier. The same goes for identifiers used in queries: A query like `SELECT foo FROM tablename` is implicitly converted to `SELECT FOO FROM TABLENAME`.

If you create your table as

```
CREATE TABLE testtab (id INTEGER PRIMARY KEY)
```

then a query like

```
SELECT * FROM testtab
```

should work fine, and

```
SELECT * FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME='TESTTAB'
```

should work, while the following query will probably fail:

```
SELECT * FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME='testtab'
```

#### Warning about `INFORMATION_SCHEMA` gotchas in PostgreSQL

Warning: PostgreSQL's case-conversion rules for unquoted identifiers (such as table names) are non-standard: PostgreSQL converts the identifiers to *lower* case, instead of converting to *upper* case. This means that you may try altering the case of identifier names used for queries in the `INFORMATION_SCHEMA` if you experience unexpected, empty metadata queries.

Note also that due to PostgreSQL's handling of constraint names, the `INFORMATION_SCHEMA` cannot safely be used to deduce referential constraints; for this, you have to use PostgreSQL's `pg_catalog` system-schema.

#### Getting a table description

Standard	<p>Part 11 of the SQL standard specifies the <code>INFORMATION_SCHEMA</code> schema which must be part of all database catalogues. The schema may be used like this:</p> <pre>SELECT column_name,data_type,column_default,is_nullable FROM     information_schema.tables AS t JOIN     information_schema.columns AS c ON         t.table_catalog=c.table_catalog AND         t.table_schema=c.table_schema AND         t.table_name=c.table_name WHERE     t.table_name='TABLE-NAME'</pre> <p>—or like this (more verbose):</p> <pre>SELECT     column_name,     data_type,     character_maximum_length,     numeric_precision,     column_default,     is_nullable</pre>
----------	---

```

information_schema.columns AS c ON
  t.table_catalog=c.table_catalog AND
  t.table_schema=c.table_schema AND
  t.table_name=c.table_name
WHERE
  c.table_schema='TABLE-SCHEMA'
AND
  c.table_name='TABLE-NAME'

```

To get information about constraints, involved columns and (possibly) referenced columns, a query like this may be used:

```

SELECT
  tc.CONSTRAINT_NAME,
  CONSTRAINT_TYPE,
  ccu.COLUMN_NAME,
  rccu.COLUMN_NAME,
  rccu.TABLE_CATALOG,
  rccu.TABLE_SCHEMA,
  rccu.TABLE_NAME,
  CHECK_CLAUSE
FROM
  INFORMATION_SCHEMA.TABLE_CONSTRAINTS tc
LEFT JOIN
  INFORMATION_SCHEMA.CONSTRAINT_COLUMN_USAGE ccu ON
    tc.CONSTRAINT_CATALOG=ccu.CONSTRAINT_CATALOG AND
    tc.CONSTRAINT_SCHEMA=ccu.CONSTRAINT_SCHEMA AND
    tc.CONSTRAINT_NAME=ccu.CONSTRAINT_NAME AND
    tc.TABLE_CATALOG=ccu.TABLE_CATALOG AND
    tc.TABLE_SCHEMA=ccu.TABLE_SCHEMA AND
    tc.TABLE_NAME=ccu.TABLE_NAME
LEFT JOIN
  INFORMATION_SCHEMA.REFERENTIAL_CONSTRAINTS rc ON
    rc.CONSTRAINT_CATALOG=ccu.CONSTRAINT_CATALOG AND
    rc.CONSTRAINT_SCHEMA=ccu.CONSTRAINT_SCHEMA AND
    rc.CONSTRAINT_NAME=ccu.CONSTRAINT_NAME
LEFT JOIN
  INFORMATION_SCHEMA.CONSTRAINT_COLUMN_USAGE rccu ON
    rc.UNIQUE_CONSTRAINT_CATALOG=rccu.CONSTRAINT_CATALOG AND
    rc.UNIQUE_CONSTRAINT_SCHEMA=rccu.CONSTRAINT_SCHEMA AND
    rc.UNIQUE_CONSTRAINT_NAME=rccu.CONSTRAINT_NAME
LEFT JOIN
  INFORMATION_SCHEMA.CHECK_CONSTRAINTS cc ON
    tc.CONSTRAINT_CATALOG=cc.CONSTRAINT_CATALOG AND
    tc.CONSTRAINT_SCHEMA=cc.CONSTRAINT_SCHEMA AND
    tc.CONSTRAINT_NAME=cc.CONSTRAINT_NAME
WHERE
  tc.TABLE_CATALOG='CATALOG-NAME' AND -- see remark
  tc.TABLE_SCHEMA='SCHEMA-NAME' AND -- see remark
  tc.TABLE_NAME='TABLE-NAME'
ORDER BY tc.CONSTRAINT_NAME

```

If you don't care about potential namespace conflicts, you may leave out the lines commented with "`-- see remark`".

See also: Warning about potential case sensitivity problems above.

**PostgreSQL** Follows the standard, except for some gotchas mentioned above.

In command-line context it's easier to use this non-SQL command:

```
\d tablename
```

**DB2** Doesn't provide the standard `INFORMATION_SCHEMA`.

To obtain (very) basic information about a table:

```
DESCRIBE TABLE tablename
DESCRIBE INDEXES FOR TABLE tablename SHOW DETAIL
```

To get information about constraints, including involved/referred columns, a query like the following may be used, although the `db2` 'utility' isn't good at adjusting column widths in output (i.e. the output is not easy to read):

```

r.refschema as ref_tabschema,
r.reftabname as ref_tabname,
kcu_r.colname as ref_colname
FROM
syscat.tabconst tc
JOIN
syscat.keycoluse kcu ON
tc.constname=kcu.constname
LEFT JOIN
syscat.references r ON
type='F' AND
tc.constname=r.constname
LEFT JOIN
syscat.keycoluse kcu_r ON
r.constname=kcu_r.constname
WHERE
tc.tabschema=UCASE('schemaname') AND
tc.tabname=UCASE('tablename')
ORDER BY const_name,col_name

```

## DOCUMENTATION:

- The DESCRIBE command in the "db2" command line processor
- SYSCAT view s

MSSQL	<p>Follows the standard, except that</p> <ul style="list-style-type: none"> <li>• MSSQL uses non-standard names for some standard datatypes, i.e. <code>varchar</code> instead of the standard's <code>CHARACTER_VARYING</code></li> <li>• MSSQL's <code>INFORMATION_SCHEMA</code> doesn't have all SQL:2008's columns (an example: MSSQL's <code>INFORMATION_SCHEMA.COLUMNS</code> view does not contain the <code>IS_IDENTITY</code> column)</li> </ul> <p>Often, the <code>SP_HELP 'tablename'</code> system stored procedure is easier to use.</p> <p>DOCUMENTATION:</p> <ul style="list-style-type: none"> <li>• Information Schema Views</li> <li>• <code>sp_help</code></li> </ul>
-------	---

MySQL	<p>Follows the standard, except that</p> <ul style="list-style-type: none"> <li>• MySQL doesn't support schemas, so one might say that MySQL's <code>INFORMATION_SCHEMA</code> is really an '<code>INFORMATION_DATABASE</code>' or '<code>INFORMATION_CATALOGUE</code>'.</li> <li>• MySQL's <code>INFORMATION_SCHEMA</code> doesn't have all SQL:2008's columns (an example: MySQL's <code>INFORMATION_SCHEMA.COLUMNS</code> view does not contain the <code>IS_IDENTITY</code> column).</li> <li>• As MySQL's namespaces don't match the SQL standard fully, the standard queries mentioned above will not work. The reason is that in MySQL, the value of <code>TABLE_CATALOG</code> is <code>NULL</code> for all tables and columns. To obtain the wanted information, you need to remove the <code>table_catalog</code> join-conditions. I.e., the first (and simplest) of the above queries must be re-written to:</li> </ul> <pre> SELECT column_name,data_type,column_default,is_nullable FROM information_schema.tables AS t JOIN information_schema.columns AS c ON t.table_schema=c.table_schema AND t.table_name=c.table_name WHERE t.table_name='TABLE-NAME' </pre> <p>In command-line context it's easier to use this non-SQL command:</p> <pre>DESCRIBE tablename</pre> <p>DOCUMENTATION:</p> <ul style="list-style-type: none"> <li>• The <code>INFORMATION_SCHEMA</code></li> <li>• <code>DESCRIBE</code></li> </ul>
-------	--

To get information on constraints, including foreign (referred) table/column information, a query like this may be used (adjust *tablename* in one of the last lines):

```

COLUMN consname FORMAT a11;
COLUMN colname FORMAT a10;
COLUMN type FORMAT a11;
COLUMN cond FORMAT a20;
COLUMN ref_tablename FORMAT a11;
COLUMN ref_colname FORMAT a11;
SELECT
    uc.constraint_name consname,
    ucc.column_name colname,
    CASE
        WHEN uc.constraint_type='C' THEN 'CHECK'
        WHEN uc.constraint_type='P' THEN 'PRIMARY KEY'
        WHEN uc.constraint_type='R' THEN 'REFERENTIAL'
        WHEN uc.constraint_type='U' THEN 'UNIQUE'
        ELSE uc.constraint_type
    END as type,
    uc.search_condition cond,
    ucc_r.table_name ref_tablename,
    ucc_r.column_name ref_colname
FROM
    user_constraints uc
JOIN
    user_cons_columns ucc ON
        uc.constraint_name=ucc.constraint_name AND
        uc.owner=ucc.owner
LEFT JOIN
    user_constraints uc_r ON
        uc.r_constraint_name=uc_r.constraint_name AND
        uc.owner=uc_r.owner
LEFT JOIN
    user_cons_columns ucc_r ON
        uc_r.constraint_name=ucc_r.constraint_name AND
        uc_r.owner=ucc_r.owner
WHERE
    uc.TABLE_NAME = UPPER('tablename')
ORDER BY consname,colname;
```

To get information on indexes on a table, a query like this may be used (adjust *tablename* in one of the last lines):

```

COLUMN index_name FORMAT a11;
COLUMN type      FORMAT a8;
COLUMN uniness   FORMAT a9;
COLUMN column_name FORMAT a20;
SELECT index_name,
       index_type type,
       uniqueness uniness,
       column_name
  FROM user_indexes ui
NATURAL JOIN user_ind_columns uic
 WHERE dropped='NO'
   AND table_name=upper('tablename')
ORDER BY index_name,column_name
```

#### DOCUMENTATION:

- DESCRIBE sqlplus command
- COLUMN sqlplus command
- Static Data Dictionary Views
- USER\_CONSTRAINTS data dictionary view
- USER\_CONS\_COLUMNS data dictionary view
- USER\_INDEXES data dictionary view
- USER\_IND\_COLUMNS data dictionary view

Informix

Doesn't provide the standard INFORMATION\_SCHEMA out of the box. If a special script is run, an INFORMATION\_SCHEMA may be added which allows for using the most basic standards based table description query

```

SELECT
    colname,
    coltype,
    CASE
        WHEN (coltype-256)<0 THEN 'YES'
        ELSE                      'NO'
    END      AS nullable
FROM    systables AS a
JOIN   syscolumns AS b   ON a.tabid = b.tabid
WHERE  tabname='tablename'

```

Notice that the table name is in lower case. The *colname* values are numeric codes which need to be looked up in order to provide meaning.

DOCUMENTATION

## Manually telling the DBMS to collect statistics

In most DBMSes, it's possible to enable automatic statistics gathering, but sometimes, it's nice to be able to manually tell the DBMS to gather statistics for a table (or a number of tables).

Standard	Not standardized.
PostgreSQL	<p>ANALYZE <i>tablename</i></p> <p>If the <i>tablename</i> parameter is left out, then statistics are gathered for all tables in the current database.</p> <p>DOCUMENTATION</p>
DB2	<p>RUNSTATS ON TABLE <i>schema-name.table-name</i> AND INDEXES ALL (many variations/options available)</p> <p>The RUNSTATS command needs to be invoked in a special way if you aren't using the db2 command line processor, namely through the ADMIN_CMD procedure.</p> <p>DOCUMENTATION: RUNSTATS and RUNSTATS wrapped in ADMIN_CMD.</p>
MSSQL	<p>First, you have to add statistics to the table:</p> <pre> CREATE STATISTICS <i>stats_name</i> ON <i>table_name</i> (<i>column_name_1, column_name_2, column_name_3, ...</i>) </pre> <p>(The CREATE STATISTICS step is not needed for indexed columns. Thus, this step may be skipped if you are satisfied with keeping statistics on indexed columns only.)</p> <p>The statistics may then be updated when needed:</p> <pre> UPDATE STATISTICS <i>table_name</i> </pre> <p>Having to explicitly mention tables and columns can be tedious, and in many cases, the sp_createstats and sp_updatestats stored procedures are easier to use.</p> <p>DOCUMENTATION: CREATE STATISTICS, UPDATE STATISTICS, sp_createstats, sp_updatestats</p>
MySQL	<p>ANALYZE TABLE <i>tablename</i></p> <p>DOCUMENTATION</p>
Oracle	<p>Oracle offers to <i>estimate</i> (quick) or <i>compute</i> (thorough) statistics for a database object. The quick way to do this is to use the deprecated ANALYZE command which can be used in various ways, e.g.</p> <pre> ANALYZE TABLE <i>tablename</i> ESTIMATE STATISTICS; ANALYZE TABLE <i>tablename</i> ESTIMATE STATISTICS FOR ALL INDEXES; </pre> <p>(It's unclear to me if both are needed to gain the relevant statistics.)</p> <p>—Or:</p> <pre> ANALYZE TABLE <i>tablename</i> COMPUTE STATISTICS; ANALYZE TABLE <i>tablename</i> COMPUTE STATISTICS FOR ALL INDEXES; </pre> <p>If you want to stay away from deprecated features (although I doubt that Oracle will remove ANALYZE..STATISTICS... any time soon), you need to use the DBMS_STATS package.</p> <p>DOCUMENTATION On my TODO.</p>
Informix	

Standard	Not standardized.
PostgreSQL	<pre>EXPLAIN &lt;query&gt;</pre> <p>DOCUMENTATION</p>
DB2	<p>The easiest way to get a query explanation is to save the query in a file (without a terminating semicolon), and then run a special command-line utility:</p> <pre>db2expln -database databasename -stmtfile query.sql -terminator ';' -terminal</pre> <p>In the above example, the query has been saved to a file called "query.sql".</p> <p>In some situations, you may want to use the <code>dynexpln</code> utility instead of <code>db2expln</code>. And in yet other situations, the <code>db2exfmt</code> tool is a better choice. A visual explanation tool also exists.</p> <p>If you prefer to get the explanation through SQL:</p> <ol style="list-style-type: none"> <li>1. Set up needed <i>explain tables</i> using <code>EXPLAIN.DDL</code> which should exist in <code>sqllib/misc</code> of your DB2 instance user's home directory.</li> <li>2. Optionally: Clean up old plan explanations: <code>DELETE FROM EXPLAIN_INSTANCE</code></li> <li>3. Generate the explanation: <code>EXPLAIN PLAN FOR &lt;SQL-statement&gt;</code></li> <li>4. Display plan:</li> </ol> <pre>SELECT O.Operator_ID, S2.Target_ID, O.Operator_Type,        S.Object_Name, CAST(O.Total_Cost AS INTEGER) Cost   FROM EXPLAIN_OPERATOR O   LEFT OUTER JOIN EXPLAIN_STREAM S2     ON O.Operator_ID=S2.Source_ID   LEFT OUTER JOIN EXPLAIN_STREAM S     ON O.Operator_ID = S.Target_ID    AND O.Explain_Time = S.Explain_Time    AND S.Object_Name IS NOT NULL  ORDER BY O.Explain_Time ASC, Operator_ID ASC</pre> <p>(Adapted from recipe in <i>SQL Tuning</i>.)</p> <p>DOCUMENTATION</p>
MSSQL	<p>MSSQL can be put in a query explanation mode where queries are not actually executed, but a query explanation is returned instead:</p> <pre>SET SHOWPLAN_TEXT ON</pre> <p>The query explanation mode is turned off by running</p> <pre>SET SHOWPLAN_TEXT OFF</pre> <p>DOCUMENTATION</p>
MySQL	<pre>EXPLAIN &lt;query&gt;</pre> <p>DOCUMENTATION</p>
Oracle	<pre>EXPLAIN PLAN FOR &lt;query&gt;</pre> <p>After the query has run, do the following to get the plan explanation:</p> <pre>SELECT plan_table_output FROM table(dbms_xplan.display())</pre> <p>DOCUMENTATION</p>
Informix	On my TODO.

## Turning on query timing

Standard	Not standardized.
PostgreSQL	<pre>\timing</pre> <p>DOCUMENTATION</p>
DB2	<p>Run the query in the "db2batch" command line processor; <code>db2batch</code> prints the elapsed time of each query.</p> <p>DOCUMENTATION</p>
MSSQL	<pre>SET STATISTICS TIME ON</pre> <p>DOCUMENTATION</p>
MySQL	MySQL's command line interface prints query times by default.
Oracle	<pre>SET TIMING ON</pre> <p>DOCUMENTATION</p>

## JDBC driver jar file name, and general documentation

PostgreSQL	The PostgreSQL JDBC Driver: postgresql- <b>version-jdbcbuild#</b> .jdbc4.jar
	DOCUMENTATION
DB2	IBM Data Server Driver for JDBC: db2jcc.jar (included in default DB2 client software installations; may also be downloaded separately, after registration)
	DOCUMENTATION
MSSQL	Microsoft's driver: sqljdbc.jar Alternative: The open source JTDS driver: jtds- <b>version</b> .jar  DOCUMENTATION: <ul style="list-style-type: none"><li>• Microsoft's driver</li><li>• The JTDS driver</li></ul>
MySQL	The MySQL Connector/J driver: mysql-connector-java- <b>version</b> -bin.jar
	DOCUMENTATION
Oracle	Oracle's JDBC drivers: ojdbc5.jar (for Java 5), ojdbc6.jar (for Java 6)
	DOCUMENTATION
Informix	IBM's Informix JDBC driver: ifxjdbc.jar (download requires registration and filling out annoying questionnaires, and an installer which only works with some JREs has to be run to unpack the driver)
	DOCUMENTATION

## JDBC driver class name

PostgreSQL	org.postgresql.Driver
	DOCUMENTATION
DB2	com.ibm.db2.jcc.DB2Driver
MSSQL	Microsoft's driver: com.microsoft.sqlserver.jdbc.SQLServerDriver JTDS' driver: net.sourceforge.jtds.jdbc.Driver
MySQL	com.mysql.jdbc.Driver
	DOCUMENTATION
Oracle	oracle.jdbc.driver.OracleDriver
Informix	com.informix.jdbc.IfxDriver

## JDBC connection URL

PostgreSQL	jdbc:postgresql:// <b>hostname/DBname</b>
	DOCUMENTATION
DB2	jdbc:db2:// <b>hostname:50000/DBname</b> or (if the database is on the local host): jdbc:db2: <b>DBname</b>
	DOCUMENTATION
MSSQL	JTDS' driver: jdbc:jtds:sqlserver://<server>[:<port>]/[<database>][;<property>=<value>[;...]]  If you need to connect to a <i>named instance</i> , see add the instance name like this: jdbc:jtds:sqlserver://<server>[:<port>]/[<database>]; <b>instance=INSTANCE_NAME</b> [;<property>=<value>[;...]]
MySQL	jdbc:mysql://[ <b>host</b> ][, <b>failoverhost</b> ] [: <b>port</b> ]/[ <b>database</b> ]?user= <b>username</b> &password= <b>password</b>
	DOCUMENTATION
Oracle	jdbc:oracle:thin:@ <b>hostname:1521:instancename</b>
Informix	jdbc:informix-sqli:// <b>hostname:9088/DBname</b> ; <b>INFORMIXSERVER=instancename</b> Use port 1526 instead of 9088 if the Informix version is <11.

## Other topics

Some DBMSes let you perform a query like this:

```
SELECT 1+1
```

answering

2

With other DBMSes, you need to insert a dummy-table expression to obtain the same result:

```
SELECT 1+1 FROM dummy-table
```

Standard	On my TODO.
PostgreSQL	<p>No need for dummy-table.</p> <p>In addition, the <code>VALUES</code> keyword may be used to produce a simple result set, without introducing a <code>FROM clause</code>, e.g.  <code>VALUES (1+1)</code>          (Note the missing <code>SELECT</code> and <code>FROM</code> keywords).</p> <p>DOCUMENTATION</p>
DB2	<p><b>Dummy-table:</b> <code>SYSIBM.SYSDUMMY1</code>.</p> <p>In addition, the <code>VALUES</code> keyword may be used to produce a simple result set, without introducing a <code>FROM clause</code>, e.g.  <code>VALUES (1+1)</code>          (Note the missing <code>SELECT</code> and <code>FROM</code> keywords).</p> <p>DOCUMENTATION</p>
MSSQL	No need for dummy-table.
MySQL	No need for dummy-table, although MySQL allows you to refer to a <code>DUAL</code> dummy-table (for Oracle compatibility).
Oracle	<b>Dummy-table:</b> <code>DUAL</code> .
Informix	<p>Informix requires that you include a <code>FROM</code> specification. In recent versions of Informix (since version 11.10), a dummy table has been included: <code>sysmaster:sysdual</code>.</p> <p>For older Informix versions, the tradition is to use code like:</p> <pre>SELECT ... FROM systables WHERE tabid=1</pre> <p>This code makes use of the fact that the <code>systables</code> table is guaranteed to contain a row where <code>tabid</code> equals 1.</p> <p>DOCUMENTATION:</p> <ul style="list-style-type: none"> <li>● The <code>sysdual</code> table</li> <li>● The <code>systables</code> table</li> </ul>

## Obtaining DBMS version

Standard	<pre>SELECT CHARACTER_VALUE   FROM INFORMATION_SCHEMA.SQL_IMPLEMENTATION_INFO  WHERE IMPLEMENTATION_INFO_NAME='DBMS VERSION'</pre>
PostgreSQL	<p>Follows the standard. An alternative, non-standard function may be used:</p> <pre>SELECT VERSION()</pre> <p>DOCUMENTATION</p>
DB2	<pre>SELECT service_level FROM SYSIBADM.ENV_INST_INFO</pre> <p>—or run the special <code>db2level</code> program.</p> <p>DOCUMENTATION: <code>SYSIBADM.ENV_INST_INFO</code> and <code>db2level</code></p>
MSSQL	<p>MSSQL's implementation of the <code>IMPLEMENTATION_SCHEMA</code> doesn't seem to include the <code>SQL_IMPLEMENTATION_INFO</code> view. Instead, you may use</p> <pre>SELECT SERVERPROPERTY('ProductVersion')</pre> <p>(just the version), or</p> <pre>SELECT @@VERSION</pre> <p>(verbose, harder to parse).</p> <p>DOCUMENTATION: <code>SERVERPROPERTY</code>, <code>@@VERSION</code></p>
MySQL	<p>MySQL's <code>INFORMATION_SCHEMA</code> doesn't include the <code>SQL_IMPLEMENTATION_INFO</code> view.</p> <p>Work-around:</p> <pre>SELECT VERSION()</pre>

DOCUMENTATION	
Informix	<p>Using SQL: <code>SELECT dbinfo('version','full') FROM systables WHERE tabid=1</code></p> <p>From the command line:  <code>onstat -</code></p> <p>DOCUMENTATION:</p> <ul style="list-style-type: none"> <li>• The dbinfo function</li> <li>• The onstat utility</li> </ul>

## Standard TCP/IP port

Product	Port#	Notes	Documentation
Standard	Not specified		
PostgreSQL	5432	For security reasons, PostgreSQL doesn't listen to non-local TCP interfaces by default.	Documentation
DB2	50000		
MSSQL	1433	By default, MSSQL Express Edition doesn't listen for TCP connections.	
MySQL	3306		
Oracle	1521		Documentation
Informix	9088 (unencrypted)	Informix versions prior to version 11, the default port was 1526.	

## Diagnostic log

Each DBMS has different ways to record diagnostic information (event logs).

Standard	Not covered by the standard.
PostgreSQL	<p>By default, PostgreSQL logs to stderr, meaning that it's highly installation specific where the diagnostic information is put; on this author's system, the default ends up in <code>/var/lib/pgsql/pgstartup.log</code>. The default can be set to something more reasonable (such as <code>syslog</code> on unix, <code>eventlog</code> on Windows) by adjusting the <code>log_destination</code> configuration parameter.</p> <p>DOCUMENTATION</p>
DB2	<p>On unix systems, DB2's diagnostic log file is called <code>db2diag.log</code> and lives in the <code>sql1ib/db2dump</code> sub-directory of the instance user's home directory. I.e., a typical full path is:  <code>/home/db2inst1/sql1ib/db2dump/db2diag.log</code></p> <p>If the file is renamed or deleted, DB2 will create a new <code>db2diag.log</code> without having to be restarted.</p> <p>DOCUMENTATION</p>
MSSQL	On my TODO.
MySQL	On my TODO.
Oracle	<p>A diagnostic directory contains a file called <code>alert_INSTANCE.log</code>. The diagnostic directory is determined by the following query:</p> <pre>SELECT value FROM v\$parameter WHERE name='background_dump_dest'</pre> <p>Examples of the diagnostic directory:</p> <ul style="list-style-type: none"> <li>• On an Oracle 11gR2 running on Linux: <code>/usr/local/oracle/diag/rdbms/INSTANCE/INSTANCE/trace</code></li> <li>• On an Oracle 9.2 running on Windows: <code>D:\oracle\admin\INSTANCE\bdump</code></li> </ul> <p>DOCUMENTATION</p>
Informix	<p>The path of the diagnostic log is defined by the <code>MSGPATH</code> configuration parameter. On a Linux installation, using default options:  <code>/opt/IBM/informix/tmp/online.log</code></p> <p>DOCUMENTATION</p>

## Related work

- Mimer Information Technology AB (makers of the Mimer SQL DBMS) has an interesting feature comparison chart, displaying what SQL:1999 features are implemented in different commercial products. May be biased because it's created by a DBMS vendor. Mimer also has lists of reserved words.

Wikipedia has a *Comparison of relational database management systems* page And a Wikibook called *SQL dialects reference* is

then how to adjust to the real World, using MS Access, MSSQL, Oracle, MySQL, PostgreSQL, and DB2. (Full disclosure note: I was *technical editor* on second edition of the book.)

- Alessandro Tanasi: *Database datatype comparison sheet*.
- Peter Gulutzan (who works for MySQL AB) has written several articles related to the subject. He has also written two related books:
  - *SQL-99 Complete, Really* (co-authored with Trudy Pelzer) is said to be good.
  - *SQL Performance Tuning* (also co-authored with Trudy Pelzer), mentions quite a few cross-product SQL issues (primarily related to performance, of course).
- Some DBMS evaluations performed at the Astrogrid Virtual Observatory (focus on spatial functionality):
  - Various comparisons of MySQL, PostgreSQL and DB2.
  - Comparison of availability and names of mathematical functions in major DBMS products.
  - Autumn '03: Comparison of DB2, MySQL, and Postgres, comparing ease of use, scalability and performance of two types of spatial joins.
  - Autumn '02: Comparison of PostgreSQL, MySQL, Oracle, SQL Server and DB2.
- *Oracle / SQL Server / DB2 / Mckoi / MySQL Database Equivalents*.
- Uday Parmar: *Open Source Database Feature Comparison Matrix*.  
Note: Created by employees of a database vendor.
- SQLite:
  - Survey of NULL-handling: *NULL Handling in SQLite Versus Other Database Engines*.
  - SQL Features That SQLite Does Not Implement
- Bowman/Emerson/Darnovsky's *The Practical SQL Handbook—Using SQL Variants* is OK for this subject, although it is rather out-dated and (worse) doesn't include any guidance on working with open source DBMSs.
- Kevin E. Kline's *SQL in a Nutshell* from O'Reilly is a good reference. O'Reilly has also published Jonathan Gennick's *SQL Pocket Guide* which looks good (but I haven't read it).
- The Analysis and Solutions Company:
  - *Building Truly Portable Database Applications in PHP* includes advice on DBMS differences (some of the presentation is PHP-specific, as the title indicates).
  - *Database Portability: Date and Timestamp Columns*.
- Jutta Horstmann *OSDBmigration*.
- Lewis Cunningham: *A comparison of data types between various databases - Oracle, MySQL, DB2, Ingres, SQL Server, Firebird, Postgres*.
- Bristle Software SQL Tips contains tips with variants for several DBMSes.
- ConnStr.net: .Net/ODBC connection strings to all sorts of database systems.
